# MATRADS, BIASSOCIAHEDRA, AND $A_{\infty}$-BIALGEBRAS 

SAMSON SANEBLIDZE And RONALD UMBLE<br>(communicated by James Stasheff)

#### Abstract

We introduce the notion of a matrad $M=\left\{M_{n, m}\right\}$ whose submodules $M_{*, 1}$ and $M_{1, *}$ are non- $\Sigma$ operads. We define the free matrad $\mathcal{H}_{\infty}$ generated by a singleton $\theta_{m}^{n}$ in each bidegree ( $m, n$ ) and realize $\mathcal{H}_{\infty}$ as the cellular chains on a new family of polytopes $\left\{K K_{n, m}=K K_{m, n}\right\}$, called biassociahedra, of which $K K_{n, 1}=K K_{1, n}$ is the associahedron $K_{n}$. We construct the universal enveloping functor from matrads to PROPs and define an $A_{\infty}$-bialgebra as an algebra over $\mathcal{H}_{\infty}$.

## 1. Introduction

Let $H$ be a DG module over a commutative ring $R$ with identity. In [11], we defined an $A_{\infty}$-bialgebra structure on $H$ in terms of a square-zero ©-product on the universal PROP $U_{H}=E n d(T H)$. In this paper we take an alternative point-of-view motivated by three classical constructions: First, chain maps Ass $\rightarrow U_{H}$ and $\mathcal{A}_{\infty} \rightarrow U_{H}$ in the category of non- $\Sigma$ operads define strictly (co)associative and $A_{\infty^{-}}$(co)algebra structures on $H$; second, there is a minimal resolution of operads $\mathcal{A}_{\infty} \rightarrow$ Ass; and third, $\mathcal{A}_{\infty}$ is realized by the cellular chains on the Stasheff associahedra $K=\sqcup K_{n}[\mathbf{7}]$, [6]. It is natural, therefore, to envision a category in which analogs of Ass and $\mathcal{A}_{\infty}$ define strictly biassociative and $A_{\infty}$-bialgebra structures on $H$.

In this paper we introduce the notion of a matrad whose distinguished objects $\mathcal{H}$ and $\mathcal{H}_{\infty}$ play the role of Ass and $\mathcal{A}_{\infty}$. But unlike the operadic case, freeness considerations are subtle since biassociative bialgebras cannot be simultaneously free and cofree. Although $\mathcal{H}$ and $\mathcal{H}_{\infty}$ are generated by singletons in each bidegree, those in $\mathcal{H}$ are module generators while those in $\mathcal{H}_{\infty}$ are matrad generators. Indeed, as a non-free matrad, $\mathcal{H}$ has two matrad generators and $\mathcal{H}_{\infty}$ is its minimal resolution. Thus $\mathcal{H}$ and $\mathcal{H}_{\infty}$ are the smallest possible constructions that control biassociative bialgebras structures and their homotopy versions (cf. [5], [12], [8]).

[^0]Given a finite sequence $\mathbf{x}$ in $\mathbb{N}$, let $|\mathbf{x}|=\sum x_{i}$. A matrad $(M, \gamma)$ is a bigraded module $M=\left\{M_{n, m}\right\}_{m, n \geqslant 1}$ together with a family of structure maps

$$
\gamma=\left\{\gamma_{\mathbf{x}}^{\mathbf{y}}: \Gamma_{p}^{\mathbf{y}}(M) \otimes \Gamma_{\mathbf{x}}^{q}(M) \rightarrow M_{|\mathbf{y}|,|\mathbf{x}|}\right\}_{\mathbf{x} \times \mathbf{y} \in \mathbb{N}^{1 \times p} \times \mathbb{N}^{q \times 1}}
$$

defined on certain submodules

$$
\Gamma_{p}^{\mathbf{y}}(M) \otimes \Gamma_{\mathbf{x}}^{q}(M) \subseteq \bigotimes_{j=1}^{q} M_{y_{j}, p} \otimes \bigotimes_{i=1}^{p} M_{q, x_{i}}
$$

and generated by certain components of the S-U diagonal $\Delta_{P}$ on permutahedra [10]; its substructures $\left(\Gamma_{1}^{\mathbf{y}}(M), \gamma\right)$ and $\left(\Gamma_{\mathbf{x}}^{1}(M), \gamma\right)$ are non- $\Sigma$ operads. We think of monomials in $\Gamma_{\mathbf{x}}^{q}(M)$ as $p$-fold tensor products of multilinear operations, each with $q$ outputs, and monomials in $\Gamma_{p}^{\mathbf{y}}(M)$ as $q$-fold tensor products of multilinear operations, each with $p$ inputs.

A general PROP, and $U_{H}$ in particular, admits a canonical matrad structure and chain maps $\mathcal{H} \rightarrow U_{H}$ and $\mathcal{H}_{\infty} \rightarrow U_{H}$ in the category of matrads define biassociative bialgebra and $A_{\infty}$-bialgebra structures on $H$. Furthermore, $\mathcal{H}_{\infty}$ is realized by the cellular chains on a new family of polytopes $K K=\bigsqcup_{m, n \geqslant 1} K K_{n, m}$, called biassociahedra, of which $K K_{m, n}=K K_{n, m}$, and $K K_{1, n}$ is the Stasheff associahedron $K_{n}$. We identify the top dimensional cell of $K K_{n, m}$ with the indecomposable matrad generator $\theta_{m}^{n}$ represented graphically by a "double corolla" with data flowing upward through $m$ input and $n$ output channels (see Figure 1). The action of the matrad product $\gamma$ on the submodule $\boldsymbol{\Theta}=\left\langle\theta_{m}^{n}\right\rangle_{m, n \geqslant 1}$ generates $\mathcal{H}_{\infty}$; we define a differential $\partial$ of degree -1 on $\theta_{m}^{n}$ and extend it as a derivation of $\gamma$ (as in Example 6.11).

$$
\left.\theta_{m}^{n} \leftrightarrow\right)_{m}^{n}:=
$$

m
Figure 1.

Among the various attempts to construct homotopy versions of bialgebras, recent independent results of Markl and Shoikhet are related to ours through the theory of PROPs: In characteristic 0 , the low-order relations in Markl's version of a homotopy bialgebra [5] agree with our $A_{\infty}$-bialgebra relations and Shoikhet's composition product on the universal preCROC [12] agrees with our prematrad operation on $U_{H}$. Thus we construct a functor from matrads to PROPs called the universal enveloping functor.

The paper is organized as follows: In Section 2 we construct the biassociahedra $K K_{n, m}$ in the range $m+n \leqslant 6$. These polytopes have a simple description in terms of the S-U diagonal $\Delta_{K}$ on associahedra [10] and demonstrate the general construction while avoiding the complicating subtleties. In Section 3 we discuss various submodules of TTM ( the tensor module of $T M$ ), which model the geometry of our construction. We introduce the notion of a prematrad in Section 4, the notion of a $k$-approximation in Section 5, and the notion of a matrad in Section 6. We construct the posets $\mathcal{P} \mathcal{P}$
and $\mathcal{K} \mathcal{K}$ in Section 7, introduce the notion of the combinatorial join of permutahedra in Section 8, and construct $P P$ and $K K$ as geometric realizations of $\mathcal{P P}$ and $\mathcal{K} \mathcal{K}$ in Section 9. We identify the cellular chains of $K K$ with the $A_{\infty}$-bialgebra matrad $\mathcal{H}_{\infty}$ and prove that the restriction of the free resolution of prematrads $\rho^{\text {pre }}: F^{\text {pre }}(\Theta) \rightarrow \mathcal{H}$ to $\mathcal{H}_{\infty}$ is a free resolution in the category of matrads.

## 2. Low Dimensional Biassociahedra

Our construction of the biassociahedra $\left\{K K_{n, m}\right\}$ in the range $1 \leqslant m, n \leqslant 4$ and $m+n \leqslant 6$ is controlled by the S-U diagonal on associahedra $K$; the polytope $K K_{n, m}$ is identical to $B_{m}^{n}$ constructed by M. Markl in [5]. In the course of his construction, Markl makes arbitrary choices, which correspond to choices we made when constructing the S-U diagonal $\Delta_{K}$. So for us, all choices in our construction were made a priori once and for all.

### 2.1. The Fraction Product

Let $\Theta=\left\langle\theta_{m}^{n} \neq 0 \mid \theta_{1}^{1}=\mathbf{1}\right\rangle_{m, n \geqslant 1}$ and let $M=\left\{M_{n, m}\right\}_{m, n \geqslant 1}$ be the free PROP generated by $\Theta$. For simplicity, we assume that $M$ is a free bigraded $\mathbb{Z}_{2}$-module; sign considerations that arise over a general ground ring will be addressed in subsequent sections. For $p, q \geqslant 1$, let $\mathbf{x} \times \mathbf{y}=\left(x_{1}, \ldots, x_{p}\right) \times\left(y_{1}, \ldots, y_{q}\right) \in \mathbb{N}^{p} \times \mathbb{N}^{q}$. In [5], M. Markl defined the submodule $S$ of special elements in $M$ whose additive generators are monomials $\alpha_{\mathbf{x}}^{\mathbf{y}}$ expressed as "elementary fractions" of the form

$$
\begin{equation*}
\alpha_{\mathbf{x}}^{\mathbf{y}}=\left(\alpha_{p}^{y_{1}} \cdots \alpha_{p}^{y_{q}}\right) /\left(\alpha_{x_{1}}^{q} \cdots \alpha_{x_{p}}^{q}\right), \tag{1}
\end{equation*}
$$

where $\alpha_{x_{i}}^{q}$ and $\alpha_{p}^{y_{j}}$ are additive generators of $S$ and the $j^{\text {th }}$ output of $\alpha_{x_{i}}^{q}$ is linked to the $i^{\text {th }}$ input of $\alpha_{p}^{y_{j}}$ (juxtaposition in the numerator and denominator denotes tensor product). Thus $\operatorname{dim} \alpha_{\mathbf{x}}^{\mathbf{y}}=\sum_{i, j} \operatorname{dim} \alpha_{x_{i}}^{q}+\operatorname{dim} \alpha_{p}^{y_{j}}$, and $\alpha_{\mathbf{x}}^{\mathbf{y}}$ is represented graphically by a connected non-planar graph under the identification $\left.\theta_{m}^{n} \leftrightarrow\right)_{m}^{n}$ (see Example 2.1). We refer to $\mathbf{x}$ and $\mathbf{y}$ as the leaf sequences of $\alpha_{\mathbf{x}}^{\mathbf{y}}$.

Let $T M$ denote the tensor module of $M$. All elementary fractions define a nonassociative fraction product $/: T M \otimes T M \rightarrow S$. For example, in the iterated fraction

$$
A / B / C=\curlywedge /(\curlywedge \mathbf{1}) /(\curlywedge \mathbf{1} 1 \mathbf{1})
$$

with $\curlywedge \leftrightarrow \theta_{2}^{1}$, we have $(A / B) / C \neq 0$ and $A /(B / C)=0$. Notationally, let $\mathbf{M}_{\mathbf{x}}^{q}=$ $M_{q, x_{1}} \otimes \cdots \otimes M_{q, x_{p}}$ and $\mathbf{M}_{p}^{\mathbf{y}}=M_{y_{1}, p} \otimes \cdots \otimes M_{y_{q}, p} ;$ then the fraction product (1) can be expressed in terms of our prematrad product $\gamma_{\mathbf{x}}^{\mathbf{y}}: \mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q} \rightarrow M_{|\mathbf{y}|,|\mathbf{x}|}$ as

$$
\left(\alpha_{p}^{y_{1}} \cdots \alpha_{p}^{y_{q}}\right) /\left(\alpha_{x_{1}}^{q} \cdots \alpha_{x_{p}}^{q}\right)=\gamma_{\mathbf{x}}^{\mathbf{y}}\left(\alpha_{p}^{y_{1}} \cdots \alpha_{p}^{y_{q}} ; \alpha_{x_{1}}^{q} \cdots \alpha_{x_{p}}^{q}\right)
$$

Note that the free action of $\gamma$ on up-rooted $m$-leaf corollas $\lambda_{m}$ (or on down-rooted $n$-leaf corollas $\gamma^{n}$ ) generates all planar rooted trees with levels (PLTs), and the projection to planar rooted trees (PRTs) by forgetting levels induces the standard operadic product.

Although the matrad $\mathcal{H}_{\infty}$ is not defined in terms of PROP, one can identify $\mathcal{H}_{\infty}$ with a proper submodule of $S$ and think of the matrad product $\gamma$ as the fraction
product restricted to $\mathcal{H}_{\infty}$. Thus we may regard the $A_{\infty}$-operad $\mathcal{A}_{\infty}$ as either

$$
\begin{align*}
& \mathcal{H}_{1, *}=\left(\left\langle\theta_{m}^{1} \mid m \geqslant 1\right\rangle / \sim, \partial\right), \text { where } \partial\left(\theta_{m}^{1}\right)=\sum_{\substack{\alpha_{m}^{1} \in \mathcal{H}_{1, *} \cdot \mathcal{H}_{1, *} \\
\operatorname{dim} \alpha_{m}^{1}=m-3}} \alpha_{m}^{1} \text { or }  \tag{2}\\
& \mathcal{H}_{*, 1}=\left(\left\langle\theta_{1}^{n} \mid n \geqslant 1\right\rangle / \sim, \partial\right), \text { where } \partial\left(\theta_{1}^{n}\right)=\sum_{\substack{\alpha_{1}^{n} \in \mathcal{H}_{*, 1}^{*,} \cdot \mathcal{H}_{*, 1} \\
\operatorname{dim} \alpha_{1}^{n}=n-3}} \alpha_{1}^{n}
\end{align*}
$$

### 2.2. Low Dimensional Matrad Products

Let us construct $\left\{\mathcal{H}_{n, m}\right\}_{m+n \leqslant 6}$ inductively as stage $\mathcal{F}_{6}$ of the increasing filtration $\mathcal{F}_{k}=\bigoplus_{m+n \leqslant k} \mathcal{H}_{n, m}$. Our construction is controlled by the S-U diagonal $\Delta_{K}$ on cellular chains of the associahedra $K$ (see Subsection 5.1 and [10]), which in the range of dimensions considered here is given by

$$
\begin{aligned}
\Delta_{K}(\lambda) & =\lambda \otimes \lambda \\
\Delta_{K}(\lambda) & =\hat{\lambda} \otimes \lambda+\lambda \otimes \lambda, \text { and } \\
\Delta_{K}(\lambda) & =\hat{\lambda} \otimes \lambda+\lambda \otimes \lambda+\lambda \otimes \lambda \\
& +\lambda \otimes \lambda+\lambda \otimes \lambda+\lambda \otimes \lambda
\end{aligned}
$$

efine $\Delta_{K}^{(0)}=\mathbf{1}$; for each $k \geqslant 1$, define the (left) $k$-fold iterate of $\Delta_{K}$ by

$$
\Delta_{K}^{(k)}=\left(\Delta_{K} \otimes \mathbf{1}^{\otimes k-1}\right) \Delta_{K}^{(k-1)}
$$

and view $\Delta_{K}^{(k)}\left(\curlywedge_{p}\right)$ as a $(p-2)$-dimensional subcomplex of $K_{p}^{\times k+1}$, and dually for $\Delta_{K}^{(k)}\left(\curlyvee^{p}\right)$.

Referring to (2) above, define $\mathcal{F}_{3}=\mathcal{H}_{1,1} \oplus \mathcal{H}_{1,2} \oplus \mathcal{H}_{2,1}$. To construct $\mathcal{F}_{4}$, use the generators of $\mathcal{F}_{3}$ to construct all possible elementary fractions with two inputs and two outputs. There are exactly two such elementary fractions, namely,

$$
\alpha_{2}^{2} \leftrightarrow \curlyvee / \curlywedge \text { and } \alpha_{11}^{11} \leftrightarrow(\curlywedge \curlywedge) /(\curlyvee \curlyvee),
$$

each of dimension zero. Let $\mathcal{H}_{2,2}=\left\langle\theta_{2}^{2}, \alpha_{2}^{2}, \alpha_{11}^{11}\right\rangle$ and define $\partial\left(\theta_{2}^{2}\right)=\alpha_{2}^{2}+\alpha_{11}^{11}$. Then $\mathcal{H}_{2,2}$ is a proper submodule of $M_{2,2}$ and $K K_{2,2}$ is an interval $I$ whose edge is identified with $\theta_{2}^{2}$ and whose vertices are identified with $\alpha_{2}^{2}$ and $\alpha_{11}^{11}$. Define $\mathcal{F}_{4}=\mathcal{F}_{3} \oplus \mathcal{H}_{1,3} \oplus$ $\mathcal{H}_{2,2} \oplus \mathcal{H}_{3,1}$.

Although all fraction products are used to construct $\mathcal{F}_{4}$, more fractions than we need appear at the next stage of the construction and beyond. Note that each numerator or denominator of $\alpha_{2}^{2}$ and $\alpha_{11}^{11}$ is an iterated S-U diagonal $\Delta_{K}^{(k)}(\curlyvee)$ or $\Delta_{K}^{(k)}(\curlywedge)$ for some $k=0,1$. Indeed, the components of $\Delta_{K}^{(k)}\left(\curlywedge_{m}\right)$ and $\Delta_{K}^{(k)}\left(\curlyvee^{n}\right)$ will determine which fraction products to admit and which to discard.

Continuing with the construction of $\mathcal{F}_{5}$, use the generators of $\mathcal{F}_{4}$ to construct all possible fractions with three inputs and two outputs. There are 18 of these: one in dimension 2, nine in dimension 1 and eight in dimension 0 . Since $K K_{2,3}$ is to have a single top dimensional (indecomposable) 2-cell, we must discard the 2-dimensional
(decomposable) generator

$$
e=\frac{\AA \AA}{Y Y Y}
$$

as well as the appropriate components of its boundary. Note that $e$ represents a square given by the Cartesian product of the three points in the denominator with the two intervals in the numerator. Thus the boundary of $e$ consists of the four edges

$$
\begin{equation*}
\frac{\lambda \lambda}{Y Y Y}, \frac{\lambda \lambda}{Y Y Y}, \frac{\lambda \lambda}{Y Y Y}, \frac{\lambda A}{Y Y Y} \tag{3}
\end{equation*}
$$

the first two of which contain components of $\Delta_{K}^{(1)}\left(\curlywedge_{3}\right)$ and $\Delta_{K}^{(2)}(\curlyvee)$ in their numerators and denominators. Our selection rule admits the first two edges and their vertices.

Express each of the factors $\alpha_{x_{i}}^{q}$ and $\alpha_{p}^{y_{j}}$ in $\alpha_{\mathbf{x}}^{\mathbf{y}}=\gamma_{\mathbf{x}}^{\mathbf{y}}\left(\alpha_{p}^{y_{1}} \cdots \alpha_{p}^{y_{q}} ; \alpha_{x_{1}}^{q} \cdots \alpha_{x_{p}}^{q}\right)$ in terms of their respective leaf sequences $\mathbf{x}_{i}, \mathbf{q}_{i}, \mathbf{y}_{j}$ and $\mathbf{p}_{j}$ so that

$$
\alpha_{\mathbf{x}}^{\mathbf{y}}=\frac{\alpha_{\mathbf{p}_{1}}^{\mathbf{y}_{1}} \cdots \alpha_{\mathbf{p}_{q}}^{\mathbf{y}_{q}}}{\alpha_{\mathbf{x}_{1}}^{\mathbf{q}_{1}} \cdots \alpha_{\mathbf{x}_{p}}^{\mathbf{q}_{p}}}
$$

Then $\left(\mathbf{p}_{1}, \ldots, \mathbf{p}_{q}\right)$ and $\left(\mathbf{q}_{1}, \ldots, \mathbf{q}_{p}\right)$ define the upper and lower contact sequences of $\alpha_{\mathbf{x}}^{\mathbf{y}}$, respectively.
Example 2.1. The upper and lower contact sequences of

$$
\begin{equation*}
\alpha_{111}^{12}=\frac{\theta_{3}^{1} \alpha_{12}^{11}}{\theta_{1}^{2} \theta_{1}^{2} \theta_{1}^{2}} \leftrightarrow \frac{\hat{\lambda} \hat{Y X}}{Y Y Y}= \tag{4}
\end{equation*}
$$

are $((3),(1,2))$ and $((2),(2),(2))$, respectively.
A non-vanishing matrad monomial of codimension 1

$$
\alpha_{\mathbf{x}}^{\mathbf{y}}=\frac{\alpha_{\mathbf{p}_{1}}^{\mathbf{y}_{1}} \cdots \alpha_{\mathbf{p}_{q}}^{\mathbf{y}_{q}}}{\alpha_{\mathbf{x}_{1}}^{\mathbf{q}_{1}} \cdots \alpha_{\mathbf{x}_{p}}^{\mathbf{q}_{p}}} \in M_{|\mathbf{y}|,|\mathbf{x}|} \text { with }|\mathbf{x}|+|\mathbf{y}| \leqslant 6
$$

satisfies the following two conditions:
(i) The upper contact sequence $\left(\mathbf{p}_{1}, \ldots, \mathbf{p}_{q}\right)$ is the list of leaf sequences in some component of $\Delta_{K}^{(q-1)}\left(\curlywedge_{p}\right)$.
(ii) The lower contact sequence $\left(\mathbf{q}_{1}, \ldots, \mathbf{q}_{p}\right)$ is the list of leaf sequences in some component of $\Delta_{K}^{(p-1)}\left(\curlyvee^{q}\right)$.
Example 2.2. The elementary fraction $\alpha_{111}^{12}=\left(\theta_{3}^{1} \alpha_{12}^{11}\right) /\left(\theta_{1}^{2} \theta_{1}^{2} \theta_{1}^{2}\right) \quad$ in Example 2.1 is a non-vanishing 2 -dimensional matrad generator since its upper contact sequence $((3),(1,2))$ is the list of leaf sequences in the component

$$
\boldsymbol{A} \otimes \boldsymbol{\lambda} \text { of } \Delta_{K}^{(1)}(\boldsymbol{\lambda})
$$

and its lower contact sequence $((2),(2),(2))$ is the list of leaf sequences in

$$
\Delta_{K}^{(2)}(\mathrm{Y})=\mathrm{Y} \otimes \mathrm{Y} \otimes \mathrm{Y}
$$

Having discarded the last two fractions in (3), our selection rule admits seven 1 -dimensional generators labeling the edges of $K K_{2,3}$. Now linearly extend the boundary map $\partial$ to these matrad generators and compute the seven admissible 0 -dimensional generators labeling the vertices of $K K_{2,3}$ (see Figure 12). Then in addition to the 2-dimensional generator $e$ and the last two 1-dimensional generators in (3), our selection rule discards the common vertex

$$
\frac{\lambda \hat{Y}}{\hat{Y} Y}
$$

Different elementary fractions may represent the same element. For example,

$$
\begin{equation*}
\frac{\lambda \hat{Y} \hat{Y}}{\hat{Y}}=\frac{\lambda \lambda}{\hat{\lambda} \hat{Y} Y} \tag{5}
\end{equation*}
$$

The associativity and unit axioms in the definition of a prematrad (see Definition 4.4 below) identify various representations such as these.

Finally, $\mathcal{H}_{2,3}$ is the proper submodule of $M_{2,3}$ generated by $\theta_{3}^{2}$ and the 14 admissible fractions $\alpha_{3}^{2}$ given by the selection rule above. Define
$\partial(X)=\frac{Y}{\lambda}+\frac{\lambda}{\lambda 1}+\frac{X}{1 \lambda}+\frac{\lambda \lambda}{X Y}+\frac{\lambda \lambda}{Y X}+\frac{\lambda \lambda}{Y Y Y}+\frac{\lambda \lambda}{Y Y Y}$.
Then $K K_{2,3}$ is the heptagon pictured in Figure 2. Since $K K_{3,2}$ is homeomorphic to $K K_{2,3}$ (see Figure 19), we simultaneously obtain $\mathcal{H}_{3,2}$. Define $\mathcal{F}_{5}=\mathcal{F}_{4} \oplus \mathcal{H}_{1,4} \oplus$ $\mathcal{H}_{2,3} \oplus \mathcal{H}_{3,2} \oplus \mathcal{H}_{4,1}$.

We continue with the construction of $\mathcal{F}_{6}$. Use the generators of $\mathcal{F}_{5}$ to construct all possible fractions with two inputs and four outputs. Using the selection rule defined above, admit all elementary fractions in dimension 2 whose upper and lower contact sequences agree with lists of leaf sequences of components in $\Delta_{K}^{(k)}\left(\curlywedge_{p}\right)$ or $\Delta_{K}^{(k)}\left(\curlyvee^{q}\right)$; these represent the 2 -faces of $K K_{4,2}$. Linearly extend the boundary map $\partial$ and compute the admissible generators in dimensions 0 and 1 . Let $\mathcal{H}_{4,2}$ be the proper submodule of $M_{4,2}$ generated by $\theta_{2}^{4}$ and all admissible fractions $\alpha_{2}^{4}$, and define

$$
\begin{aligned}
& \partial(\mathbb{X})=\frac{Y}{\lambda}+\frac{\mid Y}{X}+\frac{Y \mid}{X}+\frac{| | Y}{X}+\frac{|Y|}{X}+\frac{Y| |}{X} \\
& +\frac{\lambda X}{Y Y}+\frac{X X}{Y Y}+\frac{X \lambda}{Y Y}+\frac{\lambda \lambda X}{Y Y}+\frac{\lambda \lambda X}{Y Y}+\frac{\lambda X \lambda}{Y Y} \\
& +\frac{\lambda X \lambda}{Y Y}+\frac{X \lambda \lambda}{Y Y}+\frac{X \lambda \lambda}{Y Y}+\frac{\lambda \lambda \lambda \lambda}{Y Y}+\frac{\lambda \lambda \lambda \lambda}{Y Y} \\
& +\frac{\lambda \lambda \lambda \lambda}{Y Y}+\frac{\lambda \lambda \lambda \lambda}{Y Y}+\frac{\lambda \lambda \lambda \lambda}{Y Y}+\frac{\lambda \lambda \lambda \lambda}{Y Y} .
\end{aligned}
$$

Then $K K_{4,2}$ is the 3-dimensional polytope pictured in Figures 3 and 21.

Figure 2: The biassociahedron $K K_{2,3}$.

Again, $K K_{2,4}$ is homeomorphic to $K K_{4,2}$ (see Figure 22) and we simultaneously obtain $\mathcal{H}_{2,4}$. While similar, the calculations for $K K_{3,3}$ (see Figure 20) also involve elements such as (4); we leave this case to the reader. Define $\mathcal{F}_{6}=\mathcal{F}_{5} \oplus \mathcal{H}_{1,5} \oplus \mathcal{H}_{2,4} \oplus$ $\mathcal{H}_{3,3} \oplus \mathcal{H}_{4,2} \oplus \mathcal{H}_{5,1}$.

Note that all fractions in $\mathcal{F}_{6}$ are "operadic" in the sense that each contact sequence is identified with some component of $\Delta_{K}^{(p)}\left(\curlywedge_{q}\right)$ or $\Delta_{K}^{(p)}\left(\gamma^{q}\right)$. When $n>6$, however, $\mathcal{F}_{n}$ contains "matradic" fractions whose contact sequences are identified with components of $\Delta_{P}^{(p)}\left(\curlywedge_{q}\right)$ or $\Delta_{P}^{(p)}\left(\curlyvee^{q}\right)$, the iterated diagonal on the permutahedron $P_{q-1}$. In $\mathcal{F}_{7}$, for example, there is the fraction

$$
\frac{\frac{\lambda \lambda}{X X} \wedge \lambda}{Y Y Y Y} .
$$

Nevertheless, the low dimensional examples discussed here demonstrate the general principle, and with this in mind we proceed with the general construction.

## 3. Submodules of $T T M$

Let $M=\left\{M_{n, m}\right\}_{m, n \geqslant 1}$ be a bigraded module over a commutative ring $R$ with identity $1_{R}$. Various submodules of $T T M$ will be important in our work, the most basic of which is the $q \times p$ matrix submodule $\left(M^{\otimes p}\right)^{\otimes q}$. The name "matrix submodule" is motivated by the fact that each pair of $q \times p$ matrices $X=\left(x_{i j}\right), Y=\left(y_{i j}\right) \in \mathbb{N}^{q \times p}$ with $p, q \geqslant 1$ uniquely determines the submodule
$M_{Y, X}=\left(M_{y_{1,1}, x_{1,1}} \otimes \cdots \otimes M_{y_{1, p}, x_{1, p}}\right) \otimes \cdots \otimes\left(M_{y_{q, 1}, x_{q, 1}} \otimes \cdots \otimes M_{y_{q, p}, x_{q, p}}\right) \subset T T M$.
Fix a set of bihomogeneous module generators $G \subset M$. A monomial in $T M$ is an element of $G^{\otimes p}$ and a monomial in TTM is an element of $\left(G^{\otimes p}\right)^{\otimes q}$. Thus $A \in\left(G^{\otimes p}\right)^{\otimes q}$ is naturally represented by the $q \times p$ matrix

$$
[A]=\left[\begin{array}{ccc}
g_{x_{1,1}}^{y_{1,1}} & \cdots & g_{x_{1, p}}^{y_{1, p}} \\
\vdots & & \vdots \\
g_{x_{q, 1}}^{y_{q, 1}} & \cdots & g_{x_{q, p}}^{y_{q, p}}
\end{array}\right]
$$

Figure 3: The 2 -skeleton of $K K_{4,2}$.
with entries in $G$ and rows identified with elements of $G^{\otimes p}$. Thus $A$ is the $q$-fold tensor product of the rows of $[A]$, and we refer to $A$ as a $q \times p$ monomial (we use the symbols $A$ and $[A]$ interchangeably). Consequently,

$$
\left(M^{\otimes p}\right)^{\otimes q}=\bigoplus_{X, Y \in \mathbb{N} q \times p} M_{Y, X}
$$

and we refer to

$$
\overline{\mathbf{M}}=\bigoplus_{\substack{X, Y \in \mathbb{N}^{q \times p} \\ p, q \geqslant 1}} M_{Y, X} \text { and } \overline{\mathbf{V}}=\bigoplus_{\substack{X, Y \in \mathbb{N}^{1 \times p} \cup \mathbb{N}^{q \times 1} \\ p, q \geqslant 1}} M_{Y, X}
$$

as the matrix submodule and the vector submodule, respectively. The matrix transpose $A \mapsto A^{T}$ induces the permutation of tensor factors $\sigma_{p, q}:\left(M^{\otimes p}\right)^{\otimes q} \underset{\rightarrow}{\approx}\left(M^{\otimes q}\right)^{\otimes p}$ given by

$$
\begin{gather*}
\left(\alpha_{x_{1,1}}^{y_{1,1}} \otimes \cdots \otimes \alpha_{x_{1, p}}^{y_{1, p}}\right) \otimes \cdots \otimes\left(\alpha_{x_{q, 1}}^{y_{q, 1}} \otimes \cdots \otimes \alpha_{x_{q, p}}^{y_{q, p}}\right) \mapsto  \tag{6}\\
\left(\alpha_{x_{1,1}}^{y_{1,1}} \otimes \cdots \otimes \alpha_{x_{q, 1}}^{y_{q, 1}}\right) \otimes \cdots \otimes\left(\alpha_{x_{1, p}}^{y_{1, p}} \otimes \cdots \otimes \alpha_{x_{q, p}}^{y_{q, p}}\right)
\end{gather*}
$$

Throughout this paper, $\mathbf{x}$ and $\mathbf{y}$ denote matrices in $\mathbb{N}^{q \times p}$ with constant columns and constant rows, respectively; $\mathbf{x}$ and $\mathbf{y}$ will often be row and column matrices.

Define

$$
\overline{\mathbf{M}}_{\mathrm{row}}=\bigoplus_{\mathbf{x}, Y \in \mathbb{N}^{q \times p} ; p, q \geqslant 1} M_{Y, \mathbf{x}} \text { and } \quad \overline{\mathbf{M}}^{\mathrm{col}}=\bigoplus_{X, \mathbf{y} \in \mathbb{N}^{q \times p} ; p, q \geqslant 1} M_{\mathbf{y}, X}
$$

Consider $q \times p$ monomials

$$
A=\left[\begin{array}{ccc}
\alpha_{x_{1}}^{y_{1,1}} & \cdots & \alpha_{x_{p}}^{y_{1, p}} \\
\vdots & & \vdots \\
\alpha_{x_{1}}^{y_{q, 1}} & \cdots & \alpha_{x_{p}}^{y_{q, p}}
\end{array}\right] \in M_{Y, \mathbf{x}} \text { and } B=\left[\begin{array}{ccc}
\beta_{x_{1,1}}^{y_{1}} & \cdots & \beta_{x_{1, p}}^{y_{1}} \\
\vdots & & \vdots \\
\beta_{x_{q, 1}}^{y_{q}} & \cdots & \beta_{x_{q, p}}^{y_{q}}
\end{array}\right] \in M_{\mathbf{y}, X}
$$

The row (or coderivation) leaf sequence of $A$ is the $p$-tuple of lower (input) indices rls $A=\left(x_{1}, \ldots, x_{p}\right)$ along each row of $A$. Dually, the column (or derivation) leaf sequence of $B$ is the $q$-tuple of upper (output) indices cls $B=\left(y_{1}, \ldots, y_{q}\right)^{T}$ along each column of $B$. Pictorially, each graph in the $j^{\text {th }}$ column of $A$ has $x_{j}$ inputs and each graph in the $i^{\text {th }}$ row of $B$ has $y_{i}$ outputs (see Figure 4).

The bisequence submodule of TTM is the intersection

$$
\mathbf{M}=\overline{\mathbf{M}}_{\mathrm{row}} \cap \overline{\mathbf{M}}^{\mathrm{col}}=\bigoplus_{\mathbf{x}, \mathbf{y} \in \mathbb{N}^{q \times p} ; p, q \geqslant 1} M_{\mathbf{y}, \mathbf{x}}
$$

A $q \times p$ monomial $A \in \mathbf{M}$ is represented as a bisequence matrix

$$
A=\left[\begin{array}{ccc}
\alpha_{x_{1}}^{y_{1}} & \cdots & \alpha_{x_{p}}^{y_{1}}  \tag{7}\\
\vdots & & \vdots \\
\alpha_{x_{1}}^{y_{q}} & \cdots & \alpha_{x_{p}}^{y_{q}}
\end{array}\right]
$$

in this case $\operatorname{rls} A=\left(x_{1}, \ldots, x_{p}\right)$ and $\operatorname{cls} A=\left(y_{1}, \ldots, y_{q}\right)^{T}$. Let

$$
\left.\mathbf{M}_{\mathbf{x}}^{\mathbf{y}}=\langle A \in \mathbf{M}| \mathbf{x}=\operatorname{rls} A \text { and } \mathbf{y}=\operatorname{cls} A\right\rangle
$$

then

$$
\mathbf{M}=\bigoplus_{\substack{\mathbf{x} \times \mathbf{y} \in \mathbb{N}^{1 \times p} \times \mathbb{N}^{q \times 1} \\ p, q \geqslant 1}} \mathbf{M}_{\mathbf{x}}^{\mathbf{y}}
$$

Given a finite sequence of positive integers $\mathbf{u}=\left(u_{1}, \ldots, u_{k}\right)$, let $|\mathbf{u}|=\Sigma u_{i}$. By identifying $\left(H^{\otimes q}\right)^{\otimes p} \approx\left(H^{\otimes p}\right)^{\otimes q}$ with $(q, p) \in \mathbb{N}^{2}$, we can think of a $q \times p$ monomial $A \in \mathbf{M}_{\mathbf{x}}^{\mathbf{y}}$ as an operator on the positive integer lattice $\mathbb{N}^{2}$, pictured as an arrow $(|\mathbf{x}|, q) \mapsto(p,|\mathbf{y}|)$ (see Figure 4 and Example 4.11). While this representation is helpful conceptually, it is unfortunately not faithful.

Unless explicitly indicated otherwise, we henceforth assume that

$$
\mathbf{x} \times \mathbf{y}=\left(x_{1}, \ldots, x_{p}\right) \times\left(y_{1}, \ldots, y_{q}\right)^{T} \in \mathbb{N}^{1 \times p} \times \mathbb{N}^{q \times 1}
$$

with $p, q \geqslant 1$. When the context is clear, we will often write $\mathbf{y}$ as a row vector. The bisequence vector submodule is the intersection

$$
\mathbf{V}=\overline{\mathbf{V}} \cap \mathbf{M}=\bigoplus_{s, t \in \mathbb{N}} \mathbf{M}_{s}^{\mathbf{y}} \oplus \mathbf{M}_{\mathbf{x}}^{t}
$$

Figure 4: A $2 \times 2$ monomial in $\mathbf{M}$ and its arrow representation.

Example 3.1. Let $M=M_{1,1} \oplus M_{2,2}=\left\langle\theta_{1}^{1}\right\rangle \oplus\left\langle\theta_{2}^{2}\right\rangle$. Then the bisequence vector submodule of $T T M$ is

$$
\begin{aligned}
& \mathbf{V}=\mathbf{M}_{1}^{1} \oplus \mathbf{M}_{11}^{1} \oplus \mathbf{M}_{111}^{1} \oplus \cdots \oplus \mathbf{M}_{1}^{11} \oplus \mathbf{M}_{1}^{111} \oplus \cdots \oplus \\
& \quad \mathbf{M}_{2}^{2} \oplus \mathbf{M}_{22}^{2} \oplus \mathbf{M}_{222}^{2} \oplus \cdots \oplus \mathbf{M}_{2}^{22} \oplus \mathbf{M}_{2}^{222} \oplus \cdots \\
& \quad \approx T^{+}\left(M_{1,1}\right) \oplus T^{+}\left(M_{1,1}\right) \oplus T^{+}\left(M_{2,2}\right) \oplus T^{+}\left(M_{2,2}\right)
\end{aligned}
$$

A submodule

$$
\mathbf{W}=M \oplus \bigoplus_{\mathbf{x}, \mathbf{y} \notin \mathbb{N} ; s, t \in \mathbb{N}} \mathbf{W}_{s}^{\mathbf{y}} \oplus \mathbf{W}_{\mathbf{x}}^{t} \subseteq \mathbf{V}
$$

is telescoping if for all $\mathbf{x}, \mathbf{y}, s, t$
(i) $\mathbf{W}_{s}^{\mathbf{y}} \subseteq \mathbf{M}_{s}^{\mathbf{y}}$ and $\mathbf{W}_{\mathbf{x}}^{t} \subseteq \mathbf{M}_{\mathbf{x}}^{t}$;
(ii) $\alpha_{s}^{y_{1}} \otimes \cdots \otimes \alpha_{s}^{y_{q}} \in \mathbf{W}_{s}^{\mathbf{y}}$ implies $\alpha_{s}^{y_{1}} \otimes \cdots \otimes \alpha_{s}^{y_{j}} \in \mathbf{W}_{s}^{y_{1} \cdots y_{j}}$ for all $j<q$;
(iii) $\beta_{x_{1}}^{t} \otimes \cdots \otimes \beta_{x_{p}}^{t} \in \mathbf{W}_{\mathbf{x}}^{t}$ implies $\beta_{x_{1}}^{t} \otimes \cdots \otimes \beta_{x_{i}}^{t} \in \mathbf{W}_{x_{1} \cdots x_{i}}^{t}$ for all $i<p$.

Thus the truncation maps $\tau: \mathbf{W}_{s}^{y_{1} \cdots y_{j}} \rightarrow \mathbf{W}_{s}^{y_{1} \cdots y_{j-1}}$ and $\tau: \mathbf{W}_{x_{1} \cdots x_{i}}^{t} \rightarrow \mathbf{W}_{x_{1} \cdots x_{i-1}}^{t}$ determine the following "telescoping" sequences of submodules:

$$
\begin{aligned}
\tau\left(\mathbf{W}_{s}^{\mathbf{y}}\right) \subseteq \tau^{2}\left(\mathbf{W}_{s}^{\mathbf{y}}\right) \subseteq \cdots \subseteq \tau^{q-1}\left(\mathbf{W}_{s}^{\mathbf{y}}\right)=\mathbf{W}_{s}^{y_{1}} \\
\tau\left(\mathbf{W}_{\mathbf{x}}^{t}\right) \subseteq \tau^{2}\left(\mathbf{W}_{\mathbf{x}}^{t}\right) \subseteq \cdots \subseteq \tau^{p-1}\left(\mathbf{W}_{\mathbf{x}}^{t}\right)=\mathbf{W}_{x_{1}}^{t}
\end{aligned}
$$

In general, $\mathbf{W}_{\mathbf{x}}^{t}$ is an additive submodule of $\mathbf{M}_{x_{1}}^{t} \otimes \cdots \otimes \mathbf{M}_{x_{p}}^{t}$ and does not necessarily decompose as $B_{1} \otimes \cdots \otimes B_{p}$ with $B_{i} \subseteq \mathbf{M}_{x_{i}}^{t}$.

The telescopic extension of a telescoping submodule $\mathbf{W} \subseteq \mathbf{V}$ is the submodule of matrices $\mathcal{W} \subseteq \overline{\mathbf{M}}$ with the following properties: If $A=\left[\alpha_{x_{i, j}}^{y_{i, j}}\right]$ is a $q \times p$ monomial in $\mathcal{W}$ and
 $t$, then $\alpha_{x_{i, j}}^{t} \otimes \cdots \otimes \alpha_{x_{i, j+m}}^{t} \in \mathbf{W}_{x_{i, j}, \ldots, x_{i, j+m}}^{t}$.
 $x_{i+r, j}=s$, then $\alpha_{s}^{y_{i, j}} \otimes \cdots \otimes \alpha_{s}^{y_{i+r, j}} \in \mathbf{W}_{s}^{y_{i, j}, \ldots, y_{i+r, j}}$.
Thus if $A \in \mathbf{M}_{\mathbf{x}}^{\mathbf{y}} \cap \mathcal{W}$, the $i^{\text {th }}$ row of $A$ lies in $\mathbf{W}_{\mathbf{x}}^{y_{i}}$ and $j^{\text {th }}$ column of $A$ lies in $\mathbf{W}_{x_{j}}^{\mathbf{y}}$.

## 4. Prematrads

## 4.1. $\Upsilon$-products on $\overline{\mathrm{M}}$

Given a family of maps $\bar{\gamma}=\left\{M^{\otimes q} \otimes M^{\otimes p} \rightarrow M\right\}_{p, q \geqslant 1}$, there is a canonical extension of the component $\gamma=\left\{\gamma_{\mathbf{x}}^{\mathbf{y}}: \mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q} \rightarrow \mathbf{M}_{|\mathbf{x}|}^{|\mathbf{y}|}\right\}$ to a global product $\Upsilon: \overline{\mathbf{M}} \otimes$ $\overline{\mathbf{M}} \rightarrow \overline{\mathbf{M}}$. Pairs of bisequence matrices in $\mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q}$ are called "transverse pairs."
Definition 4.1. A pair $A \otimes B=\left[\alpha_{v_{k l}}^{y_{k l}}\right] \otimes\left[\beta_{x_{i j}}^{u_{i j}}\right]$ of $(q \times s, t \times p)$ monomials in $\overline{\mathbf{M}} \otimes \overline{\mathbf{M}}$ is a
(i) Transverse Pair (TP) if $s=t=1, u_{1, j}=q$, and $v_{k, 1}=p$ for all $j$ and $k$, i.e., setting $x_{j}=x_{1, j}$ and $y_{k}=y_{k, 1}$ gives

$$
A \otimes B=\left[\begin{array}{c}
\alpha_{p}^{y_{1}} \\
\vdots \\
\alpha_{p}^{y_{q}}
\end{array}\right] \otimes\left[\begin{array}{lll}
\beta_{x_{1}}^{q} & \cdots & \beta_{x_{p}}^{q}
\end{array}\right] \in \mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q}
$$

(ii) Block Transverse Pair (BTP) if there exist $t \times s$ block decompositions $A=$ $\left[A_{k^{\prime}, l}^{\prime}\right]$ and $B=\left[B_{i, j^{\prime}}^{\prime}\right]$ such that $A_{i l}^{\prime} \otimes B_{i l}^{\prime}$ is a TP for all $i$ and $l$.

The block sizes in a BTP decomposition are uniquely determined. Unlike the blocks in a standard block matrix, the blocks $A_{i l}^{\prime}$ (or $B_{i l}^{\prime}$ ) of a BTP $A \otimes B \in \overline{\mathbf{M}} \otimes \overline{\mathbf{M}}$ may vary in length within a given row (or column). However, if $A \otimes B \in \mathbf{M}_{p_{1} \cdots p_{s}}^{\mathbf{y}_{1} \cdots \mathbf{y}_{t}} \otimes$ $\mathbf{M}_{\mathbf{x}_{1} \cdots \mathbf{x}_{s}}^{q_{1} \cdots q_{t}}$ is a BTP, each TP $A_{i l}^{\prime} \otimes B_{i l}^{\prime} \in \mathbf{M}_{p_{l}}^{\mathbf{y}_{i}} \otimes \mathbf{M}_{\mathbf{x}_{l}}^{q_{i}}$ so that for fixed $i$ (or $l$ ) the blocks $A_{i l}^{\prime}$ (or $B_{i l}^{\prime}$ ) have constant length $q_{i}$ (or $p_{l}$ ). Furthermore, $A \otimes B \in \mathbf{M}_{\mathbf{v}}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{\mathbf{u}}$ is a BTP if and only if $\mathbf{x} \times \mathbf{y} \in \mathbb{N}^{1 \times|\mathbf{v}|} \times \mathbb{N}^{|\mathbf{u}| \times 1}$ if and only if the initial point of arrow $A$ coincides with the terminal point of arrow $B$ in $\mathbb{N}^{2}$.

Example 4.2. A $(4 \times 2,2 \times 3)$ monomial pair $A \otimes B \in \mathbf{M}_{21}^{1543} \otimes \mathbf{M}_{123}^{31}$ is a $2 \times 2$ BTP per the block decompositions

Given a family of maps $\bar{\gamma}=\left\{M^{\otimes q} \otimes M^{\otimes p} \rightarrow M\right\}_{p, q \geqslant 1}$, extend the component $\gamma=$ $\left\{\gamma_{\mathbf{x}}^{\mathbf{y}}: \mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q} \rightarrow \mathbf{M}_{|\mathbf{x}|}^{|\mathbf{y}|}\right\}$ to a global product $\Upsilon: \overline{\mathbf{M}} \otimes \overline{\mathbf{M}} \rightarrow \overline{\mathbf{M}}$ by defining

$$
\Upsilon(A \otimes B)= \begin{cases}{\left[\gamma\left(A_{i j}^{\prime} \otimes B_{i j}^{\prime}\right)\right],} & A \otimes B \text { is a BTP }  \tag{8}\\ 0, & \text { otherwise }\end{cases}
$$

where $A_{i j}^{\prime} \otimes B_{i j}^{\prime}$ is the $(i, j)^{t h}$ TP in the BTP decomposition of $A \otimes B$.

We denote the $\Upsilon$-product by "." or juxtaposition. When $A \otimes B=\left[\alpha_{p}^{y_{j}}\right]^{T} \otimes\left[\beta_{x_{i}}^{q}\right]$ is a TP , we write

$$
A B=\gamma\left(\alpha_{p}^{y_{1}}, \ldots, \alpha_{p}^{y_{q}} ; \beta_{x_{1}}^{q}, \ldots, \beta_{x_{p}}^{q}\right)
$$

As an arrow, $A B$ "transgresses" from the $x$-axis to the $y$-axis $\mathbb{N}^{2}$. When $A^{q \times s} \otimes B^{t \times p} \in \mathbf{M}_{\mathbf{v}}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{\mathbf{u}}$ is a BTP and $A_{i j}^{\prime} \otimes B_{i j}^{\prime} \in \mathbf{M}_{p_{j}}^{\mathbf{y}_{i}} \otimes \mathbf{M}_{\mathbf{x}_{j}}^{q_{i}}$ is its BTP decomposition, $A B$ is a $t \times s$ matrix in $\mathbf{M}_{\left|\mathbf{x}_{1}\right| \cdots\left|\mathbf{x}_{s}\right|}^{\left|y_{\mathbf{y}}\right| \cdots\left|\mathbf{y}_{\mathbf{t}}\right|}$. As an arrow, $A B$ runs from the initial point of $B$ to the terminal point of $A$.

Note that $\Upsilon$-products always restrict to the submodules $\overline{\mathbf{M}}_{\text {row }}$ and $\overline{\mathbf{M}}^{\text {col }}$, and consequently to $\mathbf{M}$. To see this, consider a BTP $A \otimes B \in \overline{\mathbf{M}}^{\mathrm{col}} \otimes \overline{\mathbf{M}}^{\mathrm{col}}$ with block decomposition $\left[A_{i j}^{\prime}\right] \otimes\left[B_{i j}^{\prime}\right]$. Since each entry along the $i^{t h}$ row of $B$ has $q$ outputs, each block $A_{i j}^{\prime}$ is a column of length $q$. Since all entries along a row of $A$ have the same number of outputs, the total number of outputs from each block $A_{i j}^{\prime}$ is the same for all $j$. Thus $A B \in \overline{\mathbf{M}}^{\text {col }}$ and $\Upsilon$ is closed in $\overline{\mathbf{M}}^{\text {col }}$. Dually, $\Upsilon$ is closed in $\overline{\mathbf{M}}_{\text {row }}$, and consequently, $\Upsilon$ is closed in $\mathbf{M}$.

Example 4.3. Continuing Example 4.2, the action of $\Upsilon$ on the $(4 \times 2,2 \times 3)$ monomial pair $A \otimes B \in \mathbf{M}_{21}^{1543} \otimes \mathbf{M}_{123}^{31}$ produces a $2 \times 2$ monomial in $\mathbf{M}_{33}^{10,3}$ :

In the target, $\left(\left|\mathbf{x}_{1}\right|,\left|\mathbf{x}_{2}\right|\right)=(1+2,3)$ since $\left(p_{1}, p_{2}\right)=(2,1) ;$ and $\quad\left(\left|\mathbf{y}_{1}\right|,\left|\mathbf{y}_{2}\right|\right)=$ $(1+5+4,3)$ since $\left(q_{1}, q_{2}\right)=(3,1)$. As an arrow in $\mathbb{N}^{2}, A B$ initializes at $(6,2)$ and terminates at $(2,13)$.

### 4.2. Prematrads Defined

Let $1^{1 \times p}=(1, \ldots, 1) \in \mathbb{N}^{1 \times p}$ and $1^{q \times 1}=(1, \ldots, 1)^{T} \in \mathbb{N}^{q \times 1}$; we often suppress the exponents when the context is clear.

Definition 4.4. A prematrad $(M, \gamma, \eta)$ is a bigraded $R$-module $M=\left\{M_{n, m}\right\}_{m, n \geqslant 1}$ together with a family of structure maps $\gamma=\left\{\gamma_{\mathbf{x}}^{\mathbf{y}}: \mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q} \rightarrow \mathbf{M}_{|\mathbf{x}|}^{|\mathbf{y}|}\right\}$ and a unit $\eta: R \rightarrow \mathbf{M}_{1}^{1}$ such that
(i) $\Upsilon(\Upsilon(A ; B) ; C)=\Upsilon(A ; \Upsilon(B ; C))$ whenever $A \otimes B$ and $B \otimes C$ are BTPs in $\overline{\mathbf{M}} \otimes \overline{\mathbf{M}} ;$
(ii) the following compositions are the canonical isomorphisms:

$$
\begin{aligned}
& R^{\otimes b} \otimes \mathbf{M}_{a}^{b} \xrightarrow{\eta^{\otimes b} \otimes \mathbf{1}} \mathbf{M}_{1}^{1^{b \times 1}} \otimes \mathbf{M}_{a}^{b} \xrightarrow{\gamma_{a}^{1 b \times 1}} \mathbf{M}_{a}^{b} \\
& \mathbf{M}_{a}^{b} \otimes R^{\otimes a} \xrightarrow{\mathbf{1} \otimes \eta^{\otimes a}} \mathbf{M}_{a}^{b} \otimes \mathbf{M}_{\mathbf{1}^{1 \times a}}^{1} \xrightarrow{\gamma_{11 \times a}^{b}} \mathbf{M}_{a}^{b}
\end{aligned}
$$

We denote the element $\eta\left(1_{R}\right)$ by $\mathbf{1}_{\mathbf{M}}$. A morphism of prematrads $(M, \gamma)$ and $\left(M^{\prime}, \gamma^{\prime}\right)$ is a map $f: M \rightarrow M^{\prime}$ such that $f \gamma_{\mathbf{x}}^{\mathbf{y}}=\gamma^{\prime \mathbf{y}}\left(f^{\otimes q} \otimes f^{\otimes p}\right)$ for all $\mathbf{x} \times \mathbf{y}$.

Although $\Upsilon$ fails to act associatively on $\overline{\mathbf{M}}$, Axiom (i) implies that $(A B) C=$ $A(B C)$ whenever $A, B, C \in \overline{\mathbf{M}}, A B \neq 0$, and $B C \neq 0$. On the other hand, $\Upsilon$ acts associatively on $\mathbf{M}$, which is the content of Proposition 4.7 below. Given a bisequence matrix $A^{q \times p} \in \mathbf{M}_{\mathbf{x}}^{\mathbf{y}}$, let $\mathbf{1}^{q \times|\mathbf{x}|}$ and $\mathbf{1}^{|\mathbf{y}| \times p}$ denote the (bisequence) matrices whose entries are constantly $\mathbf{1}_{\mathbf{M}}$. Then Axiom (ii) implies $\Upsilon\left(\mathbf{1}^{|\mathbf{y}| \times p} ; A\right)=A=\Upsilon\left(A ; \mathbf{1}^{q \times|\mathbf{x}|}\right)$.

In the discussion that follows, we think of a string of matrices as a composition of operators and index the matrices in the order applied (from right-to-left).

Definition 4.5. Let $M=\left\{M_{n, m}\right\}$ be a bigraded $R$-module, and let $m, n \geqslant 1$. A string of matrices $A_{s} \cdots A_{1}$ is a basic string of bidegree $(m, n)$ if
(i) $A_{1} \in \mathbf{M}_{\mathbf{x}}^{b},|\mathbf{x}|=m$,
(ii) $A_{i} \in \overline{\mathbf{M}} \backslash\left\{\mathbf{1}^{q \times p} \mid p, q \in \mathbb{N}\right\}$ for all $i$,
(iii) $A_{s} \in \mathbf{M}_{a}^{\mathbf{y}},|\mathbf{y}|=n$, and
(iv) some association of $A_{s} \cdots A_{1}$ defines a sequence of BTPs.

In particular, if $M$ is a prematrad, $A_{s} \cdots A_{1}$ is a basic string of bidegree ( $m, n$ ), and each BTP in Axiom (iv) defines a non-zero $\Upsilon$-product, then $A_{s} \cdots A_{1}$ defines a nonzero element of $\mathbf{M}_{m}^{n}=M_{n, m}$. Indeed, this is exactly the situation when a prematrad ( $M, \gamma, \eta$ ) is "free" (see Definition 4.13 below).

Lemma 4.6. Let $(M, \gamma, \eta)$ be a prematrad. Then $\Upsilon$ acts associatively on a basic string $A_{s} \cdots A_{1}$ if and only if $A_{i} \in \mathbf{M}$ for all $i$.

Proof. Suppose $\Upsilon$ acts associatively on a basic string $A_{s} \cdots A_{1}$. If $s=1,2$ there is nothing to prove, so assume that $s>2$ and $1<i<s$. Since $\Upsilon$ acts associatively, every association of $A_{s} \cdots A_{1}$ defines a sequence of BTPs. Hence

$$
B A_{i} C=\left(A_{s} \cdots A_{i+1}\right) A_{i}\left(A_{i-1} \cdots A_{1}\right)
$$

is a basic string and $B \otimes A_{i}$ and $A_{i} \otimes C$ are BTPs. So write $B=\left[b_{p}^{y_{1}} \cdots b_{p}^{y_{q}}\right]^{T}$ and $C=\left[c_{x_{1}}^{r} \cdots c_{x_{t}}^{r}\right]$; then the $i^{\text {th }}$ row of $A_{i}$ has the form $\left[a_{u_{1}}^{w_{i}} \cdots a_{u_{p}}^{w_{i}}\right]$ and the $j^{\text {th }}$ column of $A_{i}$ has the form $\left[a_{z_{j}}^{v_{1}} \cdots a_{z_{j}}^{v_{r}}\right]^{T}$. Thus $A_{i} \in \overline{\mathbf{M}}_{\text {row }} \cap \overline{\mathbf{M}}^{\mathrm{col}}=\mathbf{M}$.

Conversely, we proceed by induction on string length $s$. Consider a basic string $A B C$ with $B \in \mathbf{M}$, and suppose that $A \otimes B$ and $A B \otimes C$ are BTPs. Write

$$
A \otimes B=\left[\begin{array}{c}
a_{p}^{y_{1}} \\
\vdots \\
a_{p}^{y_{r}}
\end{array}\right] \otimes\left[\begin{array}{ccc}
b_{u_{1}}^{v_{1}} & \cdots & b_{u_{p}}^{v_{1}} \\
\vdots & & \vdots \\
b_{u_{1}}^{v_{q}} & \cdots & b_{u_{p}}^{v_{q}}
\end{array}\right]
$$

let $B^{i}$ and $B_{j}$ denote the $i^{\text {th }}$ row and $j^{\text {th }}$ column of $B$. Set $v_{0}=0$ and express $A$ as
the block matrix $\left[A^{1} \cdots A^{q}\right]^{T}$ where $A^{i}=\left[a_{p}^{y_{v_{1}+\cdots+v_{i-1}+1}} \cdots a_{p}^{y_{v_{1}+\cdots+v_{i}}}\right]^{T}$. Then

$$
A B=\left[\begin{array}{c}
A^{1} B^{1} \\
\vdots \\
A^{q} B^{q}
\end{array}\right], \quad \text { where } A^{i} B^{i}=\left[\begin{array}{c}
a_{p}^{y_{v_{1}+\cdots+v_{i-1}+1}} \\
\vdots \\
a_{p}^{y_{v_{1}+\cdots+v_{i}}}
\end{array}\right]\left[\begin{array}{lll}
b_{u_{1}}^{v_{i}} & \cdots & b_{u_{p}}^{v_{i}}
\end{array}\right]
$$

Since $A B \otimes C$ is a BTP, $C$ has the form $\left[c_{x_{1}}^{q} \cdots c_{x_{s}}^{q}\right]$, where $s=u_{1}+\cdots+u_{p}$. Set $u_{0}=0$ and express $C$ as the block matrix $\left[C_{1} \cdots C_{p}\right]$, where

$$
C_{j}=\left[\begin{array}{lll}
c_{x_{u_{1}+\cdots+u_{j-1}+1}}^{q} \cdots & c_{x_{u_{1}+\cdots+u_{j}}}^{q}
\end{array}\right] .
$$

Then

$$
B_{j} \otimes C_{j}=\left[\begin{array}{c}
b_{u_{j}}^{v_{1}} \\
\vdots \\
b_{u_{j}}^{v_{q}}
\end{array}\right] \otimes\left[c_{x_{u_{1}+\cdots+u_{j-1}+1}^{q}}^{q} \cdots c_{x_{u_{1}+\cdots+u_{j}}^{q}}^{q}\right]
$$

is a TP and $B \otimes C$ is a BTP. Therefore $(A B) C=A(B C)$ by Definition 4.4, Axiom (i). Similarly, if $B \otimes C$ and $A \otimes B C$ are BTPs, then $A \otimes B$ is a BTP.

Next consider a basic string $A B C D$ with $B, C \in \mathbf{M}$. If $B \otimes C, A \otimes B C$, and $A(B C) \otimes D$ are BTPs, $A(B C)$ is a column matrix whose entries are basic strings of the form $A_{i}\left(\left[B_{i 1} \cdots B_{i p}\right]\left[C_{i 1} \cdots C_{i p}\right]\right)$. Hence $A(B C)=(A B) C$ by the calculations above; and dually, $(B C) D=B(C D)$. Furthermore, the equalities

$$
(A(B C)) D=((A B) C) D \quad \text { and } \quad A((B C) D)=A(B(C D))
$$

imply $((A B) C) D=(A B)(C D)=A(B(C D))$.
Inductively, let $k \geqslant 4$, and assume that $\Upsilon$ acts associatively on the basic strings $A_{s} \cdots A_{1}$ of length $s \leqslant k$ with $A_{i} \in \mathbf{M}$ for all $i$, and consider a basic string $A_{k+1} \cdots A_{1}$ with $A_{j} \in \mathbf{M}$ for all $j$. Since some association of $A_{k+1} \cdots A_{1}$ defines a sequence of BTPs, there is an innermost BTP $A_{j+1} \otimes A_{j}$. Let $B=A_{j+1} A_{j}$; then $B$ is a bisequence matrix since $\Upsilon$ is closed in $\mathbf{M}$, and $\Upsilon$ acts associatively on $A_{k+1} \cdots A_{j+2} B A_{j-1} \cdots A_{1}$. If $1<j<k$, let $C=A_{k+1} \cdots A_{j+2}$ and $D=A_{j-1} \cdots A_{1}$; then $\Upsilon$ acts associatively on $C A_{j+1} A_{j} D$, completing the proof.

Proposition 4.7. Let $(M, \gamma, \eta)$ be a prematrad; then $\Upsilon$ acts associatively on $\mathbf{M}$.
Proof. If $A, B, C \in \mathbf{M}$ such that $A \otimes B$ and $A B \otimes C$ are BTPs, the entries of $(A B) C$ are basic strings on which $\Upsilon$ acts associatively by Lemma 4.6. Hence $B \otimes C$ is a BTP and $(A B) C=A(B C)$. If $A \otimes B$ is a BTP and $B \otimes C$ is not, neither is $A B \otimes C$. Dually, if $B \otimes C$ is a BTP and $A \otimes B$ is not, neither is $A \otimes B C$. In either case, $(A B) C=A(B C)=0$.

Some examples of prematrads now follow.
Remark 4.8. If $(M, \gamma, \eta)$ is a prematrad, the restrictions $\left(M_{1, *}, \gamma_{*}^{1}, \eta\right)$ and $\left(M_{*, 1}, \gamma_{1}^{*}, \eta\right)$ are non- $\Sigma$ operads in the sense of May (see [6]).

Example 4.9. A non- $\Sigma \operatorname{operad}\left(K, \gamma_{*}\right)$ with

$$
\gamma_{\mathbf{x}}: K(p) \otimes K\left(x_{1}\right) \otimes \cdots \otimes K\left(x_{p}\right) \rightarrow K(|\mathbf{x}|)
$$

is a prematrad via

$$
M_{n, m}=\left\{\begin{array}{ll}
K(m), & \text { if } n=1 \\
0, & \text { otherwise }
\end{array} \quad \text { and } \gamma_{\mathbf{x}}^{\mathbf{y}}= \begin{cases}\gamma_{\mathbf{x}}, & \text { if } \mathbf{y}=1 \\
0, & \text { otherwise }\end{cases}\right.
$$

(cf. Remark 4.8). For a discussion of the differential in the special case $K=\mathcal{A}_{\infty}$, see Example 6.11.

Example 4.10. Let $\left(K=\bigoplus_{n \geqslant 1} K(n), \gamma_{*}\right)$ and $\left(L=\bigoplus_{m \geqslant 1} L(m), \gamma^{*}\right)$ be non- $\Sigma$ operads with $K(1)=L(1)$ and the same unit $\eta$. Set

$$
M_{n, m}=\left\{\begin{array}{ll}
K(n), & \text { if } m=1 \\
L(m), & \text { if } n=1 \\
0, & \text { otherwise }
\end{array} \quad \text { and } \gamma_{\mathbf{x}}^{\mathbf{y}}= \begin{cases}\gamma_{\mathbf{x}}, & \text { if } \mathbf{y}=1 \\
\gamma^{\mathbf{y}}, & \text { if } \mathbf{x}=1 \\
0, & \text { otherwise }\end{cases}\right.
$$

then $(M, \gamma)$ is a prematrad.
Example 4.11 (The Prematrad PROP $M$ ). The free PROP $M$, with its horizontal and vertical products $\times: M_{n, m} \otimes M_{n^{\prime}, m^{\prime}} \rightarrow M_{n+n^{\prime}, m+m^{\prime}}$ and $\circ: M_{r, q} \otimes M_{q, p} \rightarrow M_{r, p}$ (cf. [1], [6]), is endowed with a canonical prematrad structure ( $M^{\text {pre }}, \gamma, \eta$ ), with $\eta$ determined by $\eta\left(1_{R}\right)=\{$ unit of the PROP $M\}$. To define the structure map $\gamma$, define $x^{0}=\mathbf{1}$ and iterate $\times$ to obtain

$$
\times^{q-1} \otimes x^{p-1}: \mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q} \longrightarrow \mathbf{M}_{p q}^{|\mathbf{y}|} \otimes \mathbf{M}_{|\mathbf{x}|}^{q p}
$$

View $\alpha_{|\mathbf{x}|}^{q p} \in \mathbf{M}_{|\mathbf{x}|}^{q p}$ as a graph with $p$ groups of $q$ outputs $\left(y_{1,1} \cdots y_{1, q}\right) \cdots\left(y_{p, 1} \cdots y_{p, q}\right)$ labeled from left-to-right. The leaf permutation

$$
\sigma_{q, p}:\left(y_{1,1} \cdots y_{1, q}\right) \cdots\left(y_{p, 1} \cdots y_{p, q}\right) \mapsto\left(y_{1,1} \cdots y_{p, 1}\right) \cdots\left(y_{1, q} \cdots y_{p, q}\right)
$$

induces a $\operatorname{map} \sigma_{q, p}^{*}: \mathbf{M}_{|\mathbf{x}|}^{q p} \rightarrow \mathbf{M}_{|\mathbf{x}|}^{p q}$. Then $\gamma$ is the sum of the compositions

$$
\begin{equation*}
\gamma_{\mathbf{x}}^{\mathbf{y}}: \mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q} \xrightarrow{x^{q-1} \otimes x^{p-1}} \mathbf{M}_{p q}^{|\mathbf{y}|} \otimes \mathbf{M}_{|\mathbf{x}|}^{q p} \xrightarrow{\mathbf{1} \otimes \sigma_{q, p}^{*}} \mathbf{M}_{p q}^{|\mathbf{y}|} \otimes \mathbf{M}_{|\mathbf{x}|}^{p q} \xrightarrow{\circ} \mathbf{M}_{|\mathbf{x}|}^{|\mathbf{y}|} . \tag{9}
\end{equation*}
$$

The induced associative product $\Upsilon$ on $\mathbf{M}$ takes values in matrices of (typically) non-planar graphs as in Figure 4. In particular, let $H$ be a free DG $R$-module of finite type and view the universal PROP $U_{H}=\operatorname{End}(T H)$ as the bigraded $R$-module $M=\left\{\operatorname{Hom}\left(H^{\otimes m}, H^{\otimes n}\right)\right\}_{n, m \geqslant 1}$. Then a $q \times p$ monomial $A \in \mathbf{M}_{\mathbf{x}}^{\mathbf{y}}$ admits a representation as an operator on $\mathbb{N}^{2}$ via the identification $\left(H^{\otimes p}\right)^{\otimes q} \leftrightarrow(p, q)$ with the action of $A$ given by the composition

$$
\begin{aligned}
\left(H^{\otimes|\mathbf{x}|}\right)^{\otimes q} \approx\left(H^{\otimes x_{1}} \otimes \cdots \otimes H^{\otimes x_{p}}\right)^{\otimes q} \xrightarrow{A}\left(H^{\otimes y_{1}}\right)^{\otimes p} \otimes \cdots \otimes\left(H^{\otimes y_{q}}\right)^{\otimes p} \\
\sigma_{y_{1}, p \otimes \cdots \otimes \sigma_{y_{q}, p}}\left(H^{\otimes p}\right)^{\otimes y_{1}} \otimes \cdots \otimes\left(H^{\otimes p}\right)^{\otimes y_{q}} \approx\left(H^{\otimes p}\right)^{\otimes|\mathbf{y}|} .
\end{aligned}
$$

This motivates the representation of a general $A$ as an arrow $(|\mathbf{x}|, q) \mapsto(p,|\mathbf{y}|)$ in $\mathbb{N}^{2}$ (see Figure 4). The map $\times^{q-1} \otimes \times^{p-1}$ in (9) is the canonical isomorphism and $\gamma$ agrees with the composition product on the universal preCROC [12].

Example 4.12 (The Universal Enveloping PROP $U$ ). Recall that the structure map $\gamma_{F P}$ in the free PROP $F P(M)$ is the sum of all possible (iterated) "horizontal" and "vertical" products $\times: M_{b, a} \otimes M_{b^{\prime}, a^{\prime}} \rightarrow M_{b+b^{\prime}, a+a^{\prime}}$ and $\circ: M_{c, b} \otimes M_{b, a} \rightarrow M_{c, a}$. Furthermore, the tensor product induces left $S_{n^{-}}$and right $S_{m}$-actions

$$
\begin{gathered}
M_{b, b} \otimes M_{b, a} \xrightarrow{\sigma \otimes \mathbf{1}} M_{b, b} \otimes M_{b, a} \xrightarrow{\gamma_{F P}} M_{b, a} \text { and } \\
M_{b, a} \otimes M_{a, a} \xrightarrow{\mathbf{1} \otimes \sigma} M_{b, a} \otimes M_{a, a} \xrightarrow{\gamma_{F P}} M_{b, a} .
\end{gathered}
$$

Note that $F P$ is functorial: Given bigraded modules $M$ and $N$, a map $f=\left\{f_{b, a}\right.$ : $\left.M_{b, a} \rightarrow N_{b, a}\right\}$ extends to a map $F P(f): F P(M) \rightarrow F P(N)$ preserving horizontal and vertical products, i.e.,

$$
F P(f)\left(M_{b, a} \times M_{b^{\prime}, a^{\prime}}\right)=f\left(M_{b, a}\right) \times f\left(M_{b^{\prime}, a^{\prime}}\right)
$$

and $F P(f)\left(M_{c, b} \circ M_{b, a}\right):=f\left(M_{c, b}\right) \circ f\left(M_{b, a}\right)$. Now if $\left(M, \gamma_{M}\right)$ is a prematrad, $\gamma_{M}$ is a component of $\gamma_{F P}$ on $\mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q}$. Let $J$ be the two-sided ideal generated by $\bigoplus_{\mathbf{x} \times \mathbf{y}}\left(\gamma_{F P}-\gamma_{M}\right)\left(\mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q}\right)$. The universal enveloping PROP of $M$ is the quotient

$$
U(M)=F P(M) / J
$$

Note that the restriction of $U$ to operads is the standard functor from operads to PROPs [1].

### 4.3. Free Prematrads

"Free prematrads" are fundamentally important. Our definition of a free prematrad (below) involves an inductive definition of the intermediate set $G^{\text {pre }}=G_{*, *}^{\text {pre }}$ in which $G_{n, m}^{\mathrm{pre}}$ is defined in terms of the set

$$
G_{[n, m]}=\bigcup_{\substack{i \leqslant m, j \leqslant n, i+j<m+n}} G_{j, i}^{\text {pre }} .
$$

We think of $G_{[n, m]}$ as an $n \times m$ array whose $(j, i)^{t h}$ cell contains $G_{j, i}^{\text {pre }}$ when $i+j<$ $m+n$ and whose $(n, m)^{t h}$ cell is empty. For example, we picture $G_{[3,4]}$ as:

Borrowing our notation for the matrix and bisequence submodules of $T T M$, we denote the set of matrices over $G_{[n, m]}$ by $\overline{\mathbf{G}}_{[n, m]}$, the set of matrices over $G^{\text {pre }}$ by $\overline{\mathbf{G}}$, and the subset of bisequence matrices in $\overline{\mathbf{G}}$ by $\mathbf{G}$.

Definition 4.13. Let $\Theta=\left\langle\theta_{m}^{n} \mid \theta_{1}^{1}=\mathbf{1} \neq 0\right\rangle_{m, n \geqslant 1}$ be a free bigraded $R$-module generated by singletons $\theta_{m}^{n}$ and set $G_{1,1}^{\mathrm{pre}}=\mathbf{1}$. Inductively, if $m+n \geqslant 3$ and $\overline{\mathbf{G}}_{[n, m]}$ has
been constructed, define

$$
G_{n, m}^{\mathrm{pre}}=\theta_{m}^{n} \cup\left\{\text { basic strings } A_{s} \cdots A_{1} \text { of bidegree }(m, n), A_{i} \in \overline{\mathbf{G}}_{[n, m]}, s \geqslant 2\right\}
$$

Let $\sim$ be the equivalence relation on $G^{\text {pre }}$ generated by $\left[A_{i j} B_{i j}\right] \sim\left[A_{i j}\right]\left[B_{i j}\right]$ if and only if $\left[A_{i j}\right] \times\left[B_{i j}\right] \in \overline{\mathbf{G}} \times \overline{\mathbf{G}}$ is a BTP, and let $F^{\text {pre }}(\Theta)=\left\langle G^{\text {pre }} / \sim\right\rangle$. The free prematrad generated by $\Theta$ is the prematrad $\left(F^{\text {pre }}(\Theta), \gamma, \eta\right)$, where $\gamma$ is juxtaposition and $\eta: R \rightarrow F_{1,1}^{\text {pre }}(\Theta)$ is given by $\eta\left(1_{R}\right)=\mathbf{1}$.
Example 4.14 (The $\mathcal{A}_{\infty}$-operad). Let $\theta_{m}=\theta_{m}^{1} \neq 0$ and $\theta^{n}=\theta_{1}^{n} \neq 0$ for all $m, n \geqslant 1$. The non-sigma operads $K=F^{\text {pre }}\left(\theta_{*}\right)$ and $L=F^{\text {pre }}\left(\theta^{*}\right)$ are isomorphic to the $\mathcal{A}_{\infty}$-operad and encode the combinatorial structure of an $A_{\infty}$-algebra and an $A_{\infty}$-coalgebra, respectively. Let $\theta_{m, i}^{p}$ denote the $1 \times p$ matrix $\left[\theta_{1} \cdots \theta_{m} \cdots \theta_{1}\right]$ with $\theta_{m}$ in the $i^{t h}$ position, and let $\theta_{q}^{n, j}$ denote the $q \times 1$ matrix $\left[\theta^{1} \cdots \theta^{n} \cdots \theta^{1}\right]^{T}$ with $\theta^{n}$ in the $j^{\text {th }}$ position. Then modulo prematrad axioms (i) and (ii), the bases for $K$ and $L$ given by Definition 4.13 are

$$
\left\{\theta_{p_{k}} \theta_{m_{k}, i_{k}}^{p_{k}} \cdots \theta_{m_{1}, i_{1}}^{p_{1}} \in K\left(m_{1}+p_{1}-1\right) \mid m_{r}=p_{r-1}-p_{r}+1\right\}
$$

and

$$
\left\{\theta_{q_{l}}^{n_{l}, j_{l}} \cdots \theta_{q_{1}}^{n_{1}, j_{1}} \theta^{q_{1}} \in L\left(n_{l}+q_{l}-1\right) \mid n_{r}=q_{r+1}-q_{r}+1\right\} .
$$

Given $A \in G_{n, m}^{\text {pre }} / \sim$, choose a representative $A_{s} \cdots A_{1} \in G_{n, m}^{\text {pre }}$. In view of Definition 4.5, Axiom (iv), some association of $A_{s} \cdots A_{1}$ defines a sequence of BTPs; thus $s-1$ successive applications of $\Upsilon$ produces a $1 \times 1$ (bisequence) representative $B$.
Definition 4.15. Let $A \in G_{n, m}^{\text {pre }} / \sim$. A factorization of $A$ is a representative $A_{s} \cdots A_{1} \in A$. A factorization $A_{s} \cdots A_{1} \in A$ is a $\Theta$-factorization if the entries of $A_{i}$ are elements of $\Theta$ for all $i$. A factorization $B_{t} \cdots B_{1} \in A$ is a bisequence factorization if $B_{i} \in \mathbf{G}$ for all $i$. A bisequence factorization $A_{s} \cdots A_{1} \in A$ is bisequence decomposable if there is a bisequence factorization $B_{t} \cdots B_{1} \in A$ such that $t>s$.

Since bisequence factorizations are basic strings of matrices, bisequence factorizations are characterized by Lemma 4.6: $A_{s} \cdots A_{1} \in A$ is a bisequence factorization if and only if $\Upsilon$ acts associatively on $A_{s} \cdots A_{1}$.

Given $A \in G^{\text {pre }} / \sim$, consider a factorization $A_{s} \cdots A_{1} \in A$. Each association of $A_{s} \cdots A_{1}$ determines a fraction, any two of which will look quite different. For example, the two associations of the bisequence $\Theta$-factorization

$$
A_{3} A_{2} A_{1}=\left[\begin{array}{c}
\theta_{2}^{2}  \tag{10}\\
\theta_{2}^{2} \\
\theta_{2}^{1}
\end{array}\right]\left[\begin{array}{cc}
\theta_{2}^{2} & \theta_{1}^{2} \\
\theta_{2}^{1} & \mathbf{1}
\end{array}\right]\left[\begin{array}{lll}
\theta_{2}^{2} & \theta_{2}^{2} & \theta_{2}^{2}
\end{array}\right] \in \mathbf{G}_{6}^{6}
$$

which are

$$
\left(A_{3} A_{2}\right) A_{1}=\left[\begin{array}{c}
{\left[\begin{array}{c}
\theta_{2}^{2} \\
\theta_{2}^{2}
\end{array}\right]\left[\begin{array}{ll}
\theta_{2}^{2} & \theta_{1}^{2}
\end{array}\right]} \\
{\left[\theta_{2}^{2}\right]\left[\begin{array}{ll}
\theta_{2}^{1} & \mathbf{1}
\end{array}\right]}
\end{array}\right]\left[\begin{array}{lll}
\theta_{2}^{2} & \theta_{2}^{2} & \theta_{2}^{2}
\end{array}\right]
$$

and

$$
A_{3}\left(A_{2} A_{1}\right)=\left[\begin{array}{c}
\theta_{2}^{2} \\
\theta_{2}^{2} \\
\theta_{2}^{2}
\end{array}\right]\left[\left[\begin{array}{c}
\theta_{2}^{2} \\
\theta_{2}^{1}
\end{array}\right]\left[\begin{array}{ll}
\theta_{2}^{2} & \theta_{2}^{2}
\end{array}\right] \quad\left[\begin{array}{c}
\theta_{1}^{2} \\
1
\end{array}\right]\left[\begin{array}{l}
\theta_{2}^{2}
\end{array}\right]\right]
$$

determine the fractions

Define the graph of $A$ to be the graph of the $1 \times 1$ representative $A^{\prime} \in A$. If a fraction $f$ represents an association of $A_{s} \cdots A_{1} \in A$, the graph of $A$ can be obtained from $f$ by removing fraction bars and making the prescribed connections.

The arrows representing the factors of $A_{s} \cdots A_{1} \in A$ form a polygonal path in $\mathbb{N}^{2}$ from the $x$-axis to the $y$-axis, and evaluating subproducts in an association changes the path. For example, the 3 -step path in Figure 5 represents the factorization $A_{3} A_{2} A_{1}$ in (10) thought of as the composition

$$
H^{\otimes 6} \longrightarrow\left(H^{\otimes 2}\right)^{\otimes 3} \xrightarrow{\text { XXX }}\left(H^{\otimes 3}\right)^{\otimes 2} \longrightarrow\left(H^{\otimes 2}\right)^{\otimes 3} \xrightarrow{\text { XY }} \xrightarrow{\sigma_{2,2} \otimes \mathbf{1}} \longrightarrow\left(H^{\otimes 2}\right)^{\otimes 3} \xrightarrow{\stackrel{\times}{\times}} \xrightarrow{\times} H^{\otimes 6}
$$

and the 2 -step paths represent the associations $\left(A_{3} A_{2}\right) A_{1}$ and $A_{3}\left(A_{2} A_{1}\right)$, where the subproducts in parentheses have been evaluated and the remaining unevaluated products are thought of as the compositions

$$
H^{\otimes 6} \xrightarrow[\longrightarrow]{\mathrm{XXX}}\left(H^{\otimes 2}\right)^{\otimes 3} \xrightarrow{\sigma_{2,3}}\left(H^{\otimes 3}\right)^{\otimes 2} \xrightarrow{\frac{\mathrm{XX}}{\mathrm{XY}}}
$$

and

$$
H^{\otimes 6} \xrightarrow{\frac{\mathrm{X} \boldsymbol{X}}{\mathrm{YX}} \frac{\mathrm{YI}}{\mathrm{X}}}\left(H^{\otimes 3}\right)^{\otimes 2} \xrightarrow{\sigma_{3,2}}\left(H^{\otimes 2}\right)^{\otimes 3} \stackrel{\stackrel{\mathrm{X}}{\mathrm{X}}}{\xrightarrow{\mathrm{X}}} H^{\otimes 6} .
$$

Figure 5: Polygonal paths of $A_{3} A_{2} A_{1}$.

In the special operadic situations of Example 4.14, every $\Theta$-factorization is a bisequence factorization, but this is not true, in general. For example, the $\Theta$-factorization

$$
B_{3} B_{2} B_{1}=\left[\begin{array}{c}
\theta_{2}^{1} \\
\theta_{2}^{1}
\end{array}\right]\left[\begin{array}{cc}
\theta_{2}^{1} & \mathbf{1} \\
\mathbf{1} & \theta_{2}^{1}
\end{array}\right]\left[\begin{array}{lll}
\theta_{1}^{2} & \theta_{1}^{2} & \theta_{1}^{2}
\end{array}\right] \in G_{2,3}^{\mathrm{pre}}(\Theta)
$$

is not a bisequence factorization since $B_{2}$ is not a bisequence matrix. Furthermore, $B_{3} B_{2} B_{1}$ only associates on the left since $B_{2} \otimes B_{1}$ is not a BTP. However, $C_{2}=B_{3} B_{2}$, $C_{1}=B_{1}$, and $C=C_{2} C_{1}$ are bisequence matrices; hence $C_{2} C_{1}$ and $C$ are bisequence factorizations of which

$$
C_{2} C_{1}=\left[\begin{array}{c}
\theta_{2}^{1}\left[\begin{array}{ll}
\theta_{2}^{1} & \mathbf{1}
\end{array}\right]  \tag{11}\\
\theta_{2}^{1}\left[\begin{array}{ll}
\mathbf{1} & \theta_{2}^{1}
\end{array}\right]
\end{array}\right]\left[\begin{array}{lll}
\theta_{1}^{2} & \theta_{1}^{2} & \theta_{1}^{2}
\end{array}\right]
$$

is bisequence indecomposable (see Figure 6).

Figure 6: Graphical representations of $C_{2} C_{1}$ and $C$.

Bisequence indecomposables are especially important, and we wish to identify a canonical bisequence indecomposable representative of a given class $A \in G_{n, m}^{\text {pre }} / \sim$. First consider a bisequence indecomposable $A_{k} \cdots A_{1} \in A$ with some $A_{i} \in\left\{\theta_{*}^{1}, \theta_{1}^{*}\right\}$. If $A_{i}=\theta_{s}^{1}$ for some $s$, then $A_{i} \cdots A_{1}$ is identified with an up-rooted PLT with $i$ levels and $m$ leaves; dually, if $A_{i}=\theta_{1}^{t}$ for some $t$, then $A_{k} \cdots A_{i}$ is identified with a down-rooted PLT with $k-i+1$ levels and $n$ leaves. Note that both situations occur in factorizations of the form $A_{k} \cdots \theta_{1}^{t} \theta_{s}^{1} \cdots A_{1}$. But in either case, the indicated PLT represents an isomorphism class of PLTs whose elements determine distinct bisequence indecomposable factorizations of $A$. For example, the isomorphic PLTs

$$
\text { Y: } \bullet \bullet \bullet \bullet \rightarrow(\bullet \bullet) \bullet \bullet \rightarrow(\bullet \bullet)(\bullet \bullet)
$$

and

$$
\text { Y: } \bullet \bullet \bullet \bullet \rightarrow \bullet \bullet(\bullet \bullet) \rightarrow(\bullet \bullet)(\bullet \bullet)
$$

respectively determine the distinct equivalent bisequence indecomposables

$$
A_{4} A_{3} A_{2} A_{1}=\left[\begin{array}{lll}
\theta_{1}^{2} & \mathbf{1} & \mathbf{1}
\end{array}\right]^{T}\left[\begin{array}{ll}
\mathbf{1} & \theta_{1}^{2}
\end{array}\right]^{T}\left[\theta_{1}^{2}\right]\left[\theta_{3}^{1}\right]
$$

and

$$
A_{4}^{\prime} A_{3}^{\prime} A_{2}^{\prime} A_{1}^{\prime}=\left[\begin{array}{lll}
\mathbf{1} & 1 & \theta_{1}^{2}
\end{array}\right]^{T}\left[\begin{array}{ll}
\theta_{1}^{2} & \mathbf{1}
\end{array}\right]^{T}\left[\theta_{1}^{2}\right]\left[\theta_{3}^{1}\right]
$$

in $G_{4,3}^{\mathrm{pre}}$.

Now recall that a PLT with $s$ levels and $t$ leaves specifies the order in which $s$ pairs of parentheses are inserted into a string of $t$ indeterminates. When faced with the situations described above, choose the factorization indexed by the PLT that successively inserts parentheses as far to the left as possible. Such factorizations have preferred operadic substrings.

Definition 4.16. A preferred factorization is a factorization with preferred operadic substrings (if any) and factors whose entries have this property. A bisequence matrix $B \in G^{\text {pre }}$ is balanced if each entry of $B$ is a preferred bisequence indecomposable factorization. A balanced factorization of $A \in G^{\text {pre }} / \sim$ is a preferred bisequence indecomposable factorization $A_{s} \cdots A_{1}$ in which $A_{i}$ is balanced for all $i$.

In the example above, $A_{4} A_{3} A_{2} A_{1}$ is the (obviously unique) balanced factorization of $A \in G_{4,3}^{\text {pre }} / \sim$. In view of Definition 4.4, Axiom (i), two associations of a basic string $A_{s} \cdots A_{1}$ that define sequences of BTPs are equal. Hence each class $A \in G_{n, m}^{\text {pre }} / \sim$ has a unique preferred factorization of maximal length. In fact:

Proposition 4.17. Each class $A \in G_{n, m}^{\mathrm{pre}} / \sim$ has a unique balanced factorization.
Proof. If $m+n \leqslant 4$, balanced factorizations of $A$ are $\Theta$-factorizations, and obviously unique. Inductively, assume the statement holds for all $B \in G_{l, k}^{\text {pre }} / \sim$ with $k \leqslant m$, $l \leqslant n$ and $k+l<m+n$, and consider a class $A \in G_{n, m}^{\mathrm{pre}} / \sim$. If $\theta_{m}^{n} \in A$, then $A$ is a balanced singleton class. Otherwise, consider the unique preferred class representative $A_{s} \cdots A_{1}$ of maximal length. If $A_{s} \cdots A_{1}$ is a bisequence factorization, it is balanced. If not, evaluate $\Upsilon$-products and obtain a bisequence factorization $B_{1} B_{2}$ of $A$. Either $B_{1}=A_{s}$ or $B_{1}=A_{s} B_{1}^{\prime}$. In either case, there is a bisequence factorization $A_{s} B$ of $A$. If $B$ is bisequence indecomposable, $A_{s} B$ is the unique balanced factorization of $A$. If not, there is a bisequence factorization $C_{1} C_{2}$ of $B$. If $C_{1}$ is bisequence indecomposable, consider $C_{2}$; otherwise, decompose $C_{1}$. Continue in this manner until the process terminates.

We now construct a set that conveniently indexes the module generators $G^{\text {pre }} / \sim$ for $F^{\text {pre }}(\Theta)$. Define a map $\phi$ that splits the projection $G^{\text {pre }} \rightarrow G^{\text {pre }} / \sim$ as follows: For each pair $(m, n)$ with $m+n \leqslant 3$, set $\phi\left(\operatorname{cls} \theta_{m}^{n}\right)=\theta_{m}^{n}$. Inductively, for each pair $(m, n)$ with $m+n \geqslant 4$, assume that $\phi$ has been defined on $G_{j, i}^{\text {pre }} / \sim$ for $i+j<m+n$. Then given a class $g \in G_{n, m}^{\text {pre }} / \sim$, define $\phi_{n, m}(g)$ to be the balanced factorization of $g$. Let $\mathcal{B}_{n, m}^{\text {pre }}=\operatorname{Im} \phi_{n, m}$ and $\mathcal{B}^{\text {pre }}=\bigcup \mathcal{B}_{n, m}^{\text {pre }}$.

Although a balanced factorization $\beta \in \mathcal{B}^{\text {pre }}$ is not a $\Theta$-factorization, there is a related PLT $\Psi(\beta)$ whose leaves are $\Theta$-factorizations. Let $\beta=B_{s} \cdots B_{1} \in \mathcal{B}^{\text {pre }}$ and set $\Psi_{1}(\beta)=\beta$. If $\beta$ is a $\Theta$-factorization, set $\Psi(\beta)=\Psi_{1}(\beta)$. Otherwise, let $\left(\beta_{k}\right)$ denote the tuple of entries of $B_{k}$ listed in row order and replace each entry $\beta_{k}$ of $\left(\beta_{k}\right)$ with its balanced factorization $\beta_{k}^{\prime} \in \mathcal{B}^{\text {pre }}$. Form the 2-level tree $\Psi_{2}(\beta)$ with root $\beta$ and leaves labeled by the entries of $\left(\beta_{k}^{\prime}\right)$ (see Example 4.18). If each $\beta_{k}^{\prime}$ is a $\Theta$ factorization, set $\Psi(\beta)=\Psi_{2}(\beta)$. Otherwise, repeat this process for each $\beta_{k}^{\prime}$, i.e., let $\Psi_{1}\left(\beta_{k}^{\prime}\right)=\beta_{k}^{\prime}$; if $\beta_{k}^{\prime}$ is not a $\Theta$-factorization, construct $\Psi_{2}\left(\beta_{k}^{\prime}\right)$. Now construct 3-level tree $\Psi_{3}(\beta)$ either by appending the tree $\Psi_{2}\left(\beta_{k}^{\prime}\right)$ to the leaf $\beta_{k}^{\prime}$ if $\beta_{k}^{\prime}$ is not a Thetafactorization, or by extending the branch of $\beta_{k}^{\prime}$ otherwise. If each level 3 entry of $\Psi_{3}(\beta)$ is a $\Theta$-factorization, set $\Psi(\beta)=\Psi_{3}(\beta)$; otherwise continue inductively. This process terminates after $r$ steps and uniquely determines an $r$-level tree $\Psi(\beta)$ whose leaves are balanced $\Theta$-factorizations.

Example 4.18. The balanced factorization

$$
\beta=\left[\begin{array}{c}
\theta_{2}^{1}\left[\begin{array}{ll}
\theta_{2}^{1} & \theta_{1}^{1}
\end{array}\right] \\
\theta_{2}^{1}\left[\begin{array}{ll}
\theta_{1}^{1} & \theta_{2}^{1}
\end{array}\right]
\end{array}\right]\left[\begin{array}{lll}
\theta_{1}^{2} & \theta_{1}^{2} & \theta_{1}^{2}
\end{array}\right]
$$

is associated with the 2-level tree

$$
\Psi(\beta)=\frac{\beta}{}+\theta_{2}^{1}\left[\begin{array}{ll}
\theta_{2}^{1} & \left.\theta_{1}^{1}\right]
\end{array} \theta_{2}^{1}\left[\begin{array}{ll}
\theta_{1}^{1} & \theta_{2}^{1}
\end{array}\right] \quad \begin{array}{lll}
\theta_{1}^{2} & \theta_{1}^{2} & \theta_{1}^{2}
\end{array} .\right.
$$

Finally, let $\mathcal{C}_{n, m}^{\text {pre }}=\left\{\Psi(\beta) \mid \beta \in \mathcal{B}_{n, m}^{\text {pre }}\right\}$; then $\mathcal{C}^{\text {pre }}=\bigcup_{m, n} \mathcal{C}_{n, m}^{\text {pre }}$ indexes the set of module generators for $F^{\text {pre }}(\Theta)$. In Subsection 6.2 we identify a subset $\mathcal{C} \subset \mathcal{C}^{\text {pre }}$ whose elements simultaneously index module generators of the "free matrad" $F(\Theta)$ and cells of the biassociahedra $K K$. This identification relates the module structure of $F(\Theta)$ to the combinatorics of permutahedra.

### 4.4. The Bialgebra Prematrad

As is the case for operads and PROPs, prematrads can be described by generators and relations.
Definition 4.19. Let $\Theta=\left\langle\theta_{1}^{1}=\mathbf{1}, \theta_{2}^{1}, \theta_{1}^{2} \mid \theta_{i}^{j} \neq 0\right\rangle$. For $A$ and $B \in F^{\text {pre }}(\Theta)$, define $A \sim B$ if $\operatorname{bideg}(A)=\operatorname{bideg}(B)$. Let $\gamma$ be the structure map induced by projection and let $\eta(1)=\mathbf{1}$. Then the bialgebra permatrad $\left(\mathcal{H}^{\text {pre }}:=F^{\text {pre }}(\Theta) / \sim, \gamma, \eta\right)$ satisfies the following axioms:
(i) Associativity: $\gamma\left(\theta_{2}^{1} ; \theta_{2}^{1}, \mathbf{1}\right)=\gamma\left(\theta_{2}^{1} ; \mathbf{1}, \theta_{2}^{1}\right)$.
(ii) Coassociativity: $\gamma\left(\theta_{1}^{2}, \mathbf{1} ; \theta_{1}^{2}\right)=\gamma\left(\mathbf{1}, \theta_{1}^{2} ; \theta_{1}^{2}\right)$.
(iii) Hopf compatibility: $\gamma\left(\theta_{1}^{2} ; \theta_{2}^{1}\right)=\gamma\left(\theta_{2}^{1}, \theta_{2}^{1} ; \theta_{1}^{2}, \theta_{1}^{2}\right)$.

Each bigraded component $\mathcal{H}_{n, m}^{\text {pre }}$ is generated by a singleton $c_{n, m}$; for example, $c_{1,2}=\theta_{2}^{1}, c_{2,1}=\theta_{1}^{2}, c_{1,3}=\gamma\left(\theta_{2}^{1} ; \theta_{2}^{1}, \mathbf{1}\right), c_{3,1}=\gamma\left(\theta_{1}^{2}, \mathbf{1} ; \theta_{1}^{2}\right), c_{2,2}=\gamma\left(\theta_{1}^{2} ; \theta_{2}^{1}\right)$, and so on. Note that $\mathcal{H}_{1, *}^{\text {pre }}$ and $\mathcal{H}_{*, 1}^{\text {pre }}$ are operads; the first is generated by $\theta_{2}^{1}$ subject to $(i)$ while the second is generated by $\theta_{1}^{2}$ subject to (ii). Both are isomorphic to the associativity operad $\mathcal{A s s}[6]$. And furthermore, for the bialgebra PROP $\mathcal{B}$ we have $\mathcal{B}^{\text {pre }}=\mathcal{H}^{\text {pre }}$ and $U\left(\mathcal{H}^{\text {pre }}\right)=\mathcal{B}$.

Given a graded $R$-module $H$, a map of prematrads $\mathcal{H}^{\text {pre }} \rightarrow U_{H}$ defines a bialgebra structure on $H$ and vise versa. Since each path of arrows from $(m, 1)$ to $(1, n)$ in $\mathbb{N}^{2}$ represents some $\Upsilon$-factorization of $c_{n, m}$ (see Figure 5), we think of all such paths as equal. Therefore $\mathcal{H}^{\text {pre }}$ is the smallest module among existing general constructions that describe bialgebras (cf. [5], [12]). Although the symmetric groups do not act on prematrads, the permutation $\sigma_{n, m}$ built into the associativity axiom minimizes the modules involved.

### 4.5. Local Prematrads

Let $M=\left\{M_{n, m}\right\}_{m, n \geqslant 1}$ be a bigraded $R$-module, let $\mathbf{W}$ be a telescoping submodule of $T T M$, let $\mathcal{W}$ be its telescopic extension, and let $\gamma_{\mathbf{w}}=\left\{\gamma_{\mathbf{x}}^{\mathbf{y}}: \mathbf{W}_{p}^{\mathbf{y}} \otimes \mathbf{W}_{\mathbf{x}}^{q} \rightarrow \mathbf{W}_{|\mathbf{x}|}^{|\mathbf{y}|}\right\}$
be a structure map. If $A \otimes B$ is a BTP in $\mathcal{W} \otimes \mathcal{W}$, each TP $A^{\prime} \otimes B^{\prime}$ in $A \otimes B$ lies in $\mathbf{W}_{p}^{\mathbf{y}} \otimes \mathbf{W}_{\mathbf{x}}^{q}$ for some $\mathbf{x}, \mathbf{y}, p, q$. Consequently, $\gamma_{\mathbf{w}}$ extends to a global product $\Upsilon: \mathcal{W} \otimes$ $\mathcal{W} \rightarrow \mathcal{W}$ as in (8). In fact, $\mathcal{W}$ is the smallest matrix submodule containing $\mathbf{W}$ on which $\Upsilon$ is well-defined.

Definition 4.20. Let $\mathbf{W}$ be a telescoping submodule of $T T M$, let

$$
\gamma_{\mathbf{w}}=\left\{\gamma_{\mathbf{x}}^{\mathbf{y}}: \mathbf{W}_{p}^{\mathbf{y}} \otimes \mathbf{W}_{\mathbf{x}}^{q} \rightarrow \mathbf{W}_{|\mathbf{x}|}^{|\mathbf{y}|}\right\}
$$

be a structure map, and let $\eta: R \rightarrow \mathbf{M}$. The triple $\left(M, \gamma_{\mathbf{w}}, \eta\right)$ is a local prematrad (with domain $\mathbf{W}$ ) if the following axioms are satisfied:
(i) $\mathbf{W}_{\mathbf{x}}^{1}=\mathbf{M}_{\mathbf{x}}^{1}$ and $\mathbf{W}_{1}^{\mathbf{y}}=\mathbf{M}_{1}^{\mathbf{y}}$ for all $\mathbf{x}, \mathbf{y}$;
(ii) $\Upsilon$ is associative on $\mathcal{W} \cap \mathbf{M}$;
(iii) the prematrad unit axiom holds for $\gamma_{\mathbf{w}}$.

Example 4.21. Let $\mathbf{V}$ be the bisequence vector submodule of $T T M$. If $(M, \gamma)$ is a prematrad, then $\gamma=\gamma_{\mathbf{v}}$ and $(M, \gamma)$ is a local prematrad with domain $\mathbf{V}$. Local subprematrads $\left(M, \gamma_{\mathbf{w}}\right) \subset(M, \gamma)$ are obtained by restricting the domain to submodules such as $\mathbf{M}_{1}^{*}, \mathbf{M}_{*}^{1}$, and $\mathbf{M}_{*}^{1} \cup \mathbf{M}_{1}^{*}$. Note that $\left(M, \gamma_{\mathbf{M}_{1}^{*}}\right)$ and $\left(M, \gamma_{\mathbf{M}_{*}^{1}}\right)$ are operads.

## 5. Diagonal Approximations

A diagonal approximation $\Delta_{X}$ on a cellular complex $X$ determines a " $k$-subdivision" $X^{(k)}$ of $X$ and a cellular inclusion $\Delta^{(k)}: X^{(k)} \hookrightarrow X^{\times k+1}$ whose image is the subcomplex of $X^{\times k+1}$ we shall denote by $\Delta^{(k)}(X)$. In particular, the subcomplex $\Delta^{(k)}\left(P_{n}\right) \subset P_{n}^{\times k+1}$ determined by the S -U diagonal $\Delta_{P}$ defines the selection rule in Subsection 2.2 and, more generally, in the next section.

Recall that a map $f: X \rightarrow Y$ of $C W$-complexes is homotopic to a cellular map $g: X \rightarrow Y$, which in turn induces a chain map $g: C_{*}(X) \rightarrow C_{*}(Y)$. Given a geometric diagonal $\Delta: X \rightarrow X \times X$, a cellular map $\Delta_{X}: X \rightarrow X \times X$ homotopic to $\Delta$ is called a diagonal approximation. A diagonal approximation $\Delta_{X}$ induces a chain map $\Delta_{X}: C_{*}(X) \rightarrow C_{*}(X) \otimes C_{*}(X)$, called a diagonal. A brief review of the $\mathrm{S}-\mathrm{U}$ diagonals $\Delta_{P}$ and $\Delta_{K}$ on cellular chains of permutahedra $P=\sqcup_{n \geqslant 1} P_{n}$ and associahedra $K=\sqcup_{n \geqslant 2} K_{n}$ (up to sign) now follows (see [10] for details).

### 5.1. The S-U Diagonals $\Delta_{P}$ and $\Delta_{K}$

Let $\underline{n}=\{1,2, \ldots, n\}, n \geqslant 1$. A matrix $E$ with entries from $\{0\} \cup \underline{n}$ is a step matrix if the following conditions hold:
(i) Each element of $\underline{n}$ appears as an entry of $E$ exactly once.
(ii) Elements of $\underline{n}$ in each row and column of $E$ form an increasing contiguous block.
(iii) Each diagonal parallel to the main diagonal of $E$ contains exactly one element of $\underline{n}$.
The non-zero entries in a step matrix form a continuous staircase connecting the lower-left and upper-right most entries. There is a bijective correspondence between step matrices with non-zero entries in $\underline{n}$ and permutations of $\underline{n}$.

Given a $q \times p$ integer matrix $M=\left(m_{i j}\right)$, choose proper subsets
$S_{i} \subset\{$ non-zero entries in row $(i)\}$ and $T_{j} \subset\{$ non-zero entries in $\operatorname{col}(j)\}$, and define down-shift and right-shift operations $D_{S_{i}}$ and $R_{T_{j}}$ on $M$ as follows:
(i) If $S_{i} \neq \varnothing$, $\max \operatorname{row}(i+1)<\min S_{i}=m_{i j}$, and $m_{i+1, k}=0$ for all $k \geqslant j$, then $D_{S_{i}} M$ is the matrix obtained from $M$ by interchanging each $m_{i k} \in S_{i}$ with $m_{i+1, k}$; otherwise $D_{S_{i}} M=M$.
(ii) If $T_{j} \neq \varnothing$, $\max \operatorname{col}(j+1)<\min T_{j}=m_{i j}$, and $m_{k, j+1}=0$ for all $k \geqslant i$, then $R_{T_{j}} M$ is the matrix obtained from $M$ by interchanging each $m_{k, j} \in T_{j}$ with $m_{k, j+1}$; otherwise $R_{T j} M=M$.
Given a $q \times p$ step matrix $E$ together with subsets $S_{1}, \ldots, S_{q}$ and $T_{1}, \ldots, T_{p}$ as above, there is the derived matrix

$$
R_{T_{p}} \cdots R_{T_{2}} R_{T_{1}} D_{S_{q}} \cdots D_{S_{2}} D_{S_{1}} E .
$$

In particular, step matrices are derived matrices under the trivial action with $S_{i}=T_{j}=\varnothing$ for all $i, j$.

Let $a=A_{1}\left|A_{2}\right| \cdots \mid A_{p}$ and $b=B_{q}\left|B_{q-1}\right| \cdots \mid B_{1}$ be partitions of $\underline{n}$. Then $a \times b$ is a $(p, q)$-complementary pair (CP) if there is a $q \times p$ derived matrix $M=\left(m_{i j}\right)$ such that $A_{j}=\left\{m_{i j} \neq 0 \mid 1 \leqslant i \leqslant q\right\}$ and $B_{i}=\left\{m_{i j} \neq 0 \mid 1 \leqslant j \leqslant p\right\}$. Thus $(p, q)$-CPs, which are in one-to-one correspondence with derived matrices, identify a particular set of product cells in $P_{n} \times P_{n}$.

Definition 5.1. Define $\Delta_{P}: C_{0}\left(P_{1}\right) \rightarrow C_{0}\left(P_{1}\right) \otimes C_{0}\left(P_{1}\right)$ by $\Delta_{P}(\underline{1})=\underline{1} \otimes \underline{1}$. Inductively, having defined $\Delta_{P}: C_{*}\left(P_{k}\right) \rightarrow C_{*}\left(P_{k}\right) \otimes C_{*}\left(P_{k}\right)$ for all $k \leqslant n$, define $\Delta_{P}$ on $\underline{n+1} \in C_{n}\left(P_{n+1}\right)$ by

$$
\Delta_{P}(\underline{n+1})=\sum_{\substack{(p, q)-\mathrm{CP}, a \times b \\ p+q=n+2}} \pm a \otimes b
$$

and extend $\Delta_{P}$ multiplicatively, i.e., $\Delta_{P}\left(u_{1}|\cdots| u_{r}\right)=\Delta_{P}\left(u_{1}\right)|\cdots| \Delta_{P}\left(u_{r}\right)$.
The diagonal $\Delta_{p}$ induces a diagonal $\Delta_{K}$ on $C_{*}(K)$. Recall that faces of $P_{n}$ in codimension $k$ are indexed by PLTs with $n+1$ leaves and $k+1$ levels, and forgetting levels defines the cellular projection $\vartheta_{0}: P_{n} \rightarrow K_{n+1}$ given by A. Tonks [15]. Thus faces of $P_{n}$ indexed by PLTs with multiple nodes in the same level degenerate under $\vartheta_{0}$, and corresponding generators span the kernel of the induced map $\vartheta_{0}: C_{*}\left(P_{n}\right) \rightarrow$ $C_{*}\left(K_{n+1}\right)$. The diagonal $\Delta_{K}$ is given by

$$
\Delta_{K} \vartheta_{0}=\left(\vartheta_{0} \otimes \vartheta_{0}\right) \Delta_{P} .
$$

## 5.2. $k$-Subdivisions and $k$-Approximations

When $X$ is a polytope one can choose a diagonal approximation $\Delta_{X}: X \rightarrow X \times X$ such that
(i) $\Delta_{X}$ acts on each face $e \subset X$ as a (topological) inclusion $\Delta_{X}(e) \subset e \times e$, and
(ii) there is an induced (cellular)1-subdivision $X^{(1)}$ of $X$ that converts $\Delta_{X}$ into a cellular inclusion $\Delta_{X}^{(1)}: X^{(1)} \rightarrow X \times X$.

If $e=\bigcup_{i=1}^{m} e_{i}$ and $e_{i} \subseteq X^{(1)}$, there are faces $u_{i}, v_{i} \subseteq e_{i}$ such that $\Delta_{X}^{(1)}\left(e_{i}\right)=u_{i} \times v_{i}$. Thus $\Delta_{X}(e)=\bigcup_{i=1}^{m} \Delta_{X}^{(1)}\left(e_{i}\right)=\bigcup_{i=1}^{m} u_{i} \times v_{i}$, and in particular, $\Delta_{X}^{(1)}$ agrees with the geometric diagonal $\Delta$ only on vertices of $X$.

The 1-subdivision $X^{(1)}$ arising from an explicit diagonal approximation $\Delta_{X}$ can be thought of as the cell complex obtained by gluing the cells in $\Delta_{X}(X)$ together along their common boundaries in the only way possible. For example, the A-W diagonal on the simplex $\Delta^{n}$, the Serre diagonal on the cube $I^{n}$, and the S-U diagonals on the permutahedron $P_{n+1}$ and the associahedron $K_{n+2}$ (see [10]) induce explicit 1-subdivisions $\left(\Delta^{n}\right)^{(1)},\left(I^{n}\right)^{(1)}, P_{n+1}^{(1)}$ and $K_{n+2}^{(1)}$ (see Figures 7-10), and it is a good exercise to determine how the vertices of $\left(I^{n}\right)^{(1)}$ resolve in $P_{n+1}^{(1)}$ and $K_{n+2}^{(1)}$.

Algebraically, the assignment

$$
\begin{equation*}
e \mapsto\left\{u_{i} \times v_{i}\right\}_{1 \leqslant i \leqslant m} \tag{12}
\end{equation*}
$$

determines a DG diagonal $\Delta_{X}: C_{*}(X) \rightarrow C_{*}(X) \otimes C_{*}(X)$ on cellular chains such that $\Delta_{X}\left(C_{*}(X)\right) \subseteq C_{*}\left(\Delta_{X}^{(1)}\left(X^{(1)}\right)\right)$, where equality holds in the (unique) case $X=*$. Conversely, if a DG diagonal approximation $\Delta_{X}$ on $C_{*}(X)$ is determined by a cellular decomposition as in (12), there is a corresponding 1-subdivision $X^{(1)}$ and a 1-approximation $\Delta_{X}^{(1)}: X^{(1)} \rightarrow X \times X$.

Furthermore, there is a 2-subdivision $X^{(2)}$ of $X$ (see Figure 11) and a corresponding 2-approximation $\tilde{\Delta}_{X}^{(2)}: X^{(2)} \rightarrow X^{(1)} \times X$ that sends each cell of $X^{(2)}$ onto a single cell of $X^{(1)} \times X$; consequently, the composition $\Delta_{X}^{(2)}=\left(\Delta_{X}^{(1)} \times \mathbf{1}\right) \tilde{\Delta}_{X}^{(2)}$ sends each cell of $X^{(2)}$ onto a single cell of $X^{\times 3}$. Inductively, for each $k$, there is a $k$-subdivision $X^{(k)}$ and a $k$-approximation $\tilde{\Delta}_{X}^{(k)}: X^{(k)} \rightarrow X^{(k-1)} \times X$ such that $\Delta_{X}^{(k)}=\left(\Delta_{X}^{(k-1)} \times \mathbf{1}\right) \tilde{\Delta}_{X}^{(k)}$ sends each cell of $X^{(k)}$ onto a single cell of $X^{\times k+1}$. Thus, for each $k \geqslant 0$, a diagonal approximation $\Delta_{X}$ fixes the subcomplex $\Delta^{(k)}(X):=\Delta_{X}^{(k)}\left(X^{(k)}\right) \subset X^{\times k+1}$, which says that $\Delta_{X}$ acts on $\Delta^{(k)}(X)$ as an inclusion.

Figure 7: The 1-subdivision of $P_{2}=K_{3}=I$.

The subcomplex $\Delta^{(k)}\left(P_{n}\right) \subset P_{n}^{\times k+1}$ defines the "configuration module" of a local prematrad in the next section.

## 6. Matrads

In this section we introduce the objects in the category of matrads; morphisms require a relative theory constructed in the sequel. As motivation, let $\Theta=\left\langle\theta_{m}^{n} \neq 0\right|$ $\left.\theta_{1}^{1}=\mathbf{1}\right\rangle_{m, n \geqslant 1}$, and consider the canonical projection $\rho^{\text {pre }}: F^{\text {pre }}(\Theta) \rightarrow \mathcal{H}^{\text {pre }}$; then

Figure 8: 1-subdivisions of $\Delta^{2}$ and $\Delta^{3}$ via the A-W diagonal.

Figure 9: 1-subdivisions of $I^{2}$ and $I^{3}$ via the Serre diagonal.

Figure 10: 1-subdivisions of $P_{3}$ and $K_{4}$ via S-U diagonals $\Delta_{P}$ and $\Delta_{K}$.

Figure 11: 2-subdivisions of $P_{3}$ and $K_{4}$.

$$
\rho^{\text {pre }}\left(\theta_{m}^{n}\right)= \begin{cases}\theta_{m}^{n}, & m+n \leqslant 3 \\ 0, & \text { otherwise }\end{cases}
$$

Now consider a differential $\partial^{\text {pre }}$ on $F^{\text {pre }}(\Theta)$ such that $\rho^{\text {pre }}$ is a free resolution in the category of prematrads. Then the induced isomorphism $\varrho_{*}^{\text {pre }}: H_{*}\left(F^{\text {pre }}(\Theta), \partial^{\text {pre }}\right) \approx$ $\mathcal{H}^{\text {pre }}$ implies

$$
\begin{gathered}
\partial^{\mathrm{pre}}\left(\theta_{2}^{1}\right)=\partial^{\mathrm{pre}}\left(\theta_{1}^{2}\right)=0 \\
\partial^{\mathrm{pre}}\left(\theta_{3}^{1}\right)=\gamma\left(\theta_{2}^{1} ; \mathbf{1}, \theta_{2}^{1}\right)-\gamma\left(\theta_{2}^{1} ; \theta_{2}^{1}, \mathbf{1}\right) \\
\partial^{\mathrm{pre}}\left(\theta_{2}^{2}\right)=\gamma\left(\theta_{1}^{2} ; \theta_{2}^{1}\right)-\gamma\left(\theta_{2}^{1} \theta_{2}^{1} ; \theta_{1}^{2} \theta_{1}^{2}\right) \\
\partial^{\mathrm{pre}}\left(\theta_{1}^{3}\right)=\gamma\left(\mathbf{1}, \theta_{1}^{2} ; \theta_{1}^{2}\right)-\gamma\left(\theta_{1}^{2}, \mathbf{1} ; \theta_{1}^{2}\right)
\end{gathered}
$$

However, defining $\partial^{\text {pre }}$ on all of $\Theta$ is quite subtle, and while it is possible to canonically extend $\partial^{\text {pre }}$ to all of $\Theta$, acyclicity is difficult to verify. Instead, there is a canonical proper submodule $\mathcal{H}_{\infty} \subset F^{\text {pre }}(\Theta)$ and a differential $\partial$ on $\mathcal{H}_{\infty}$ such that the canonical projection $\varrho: \mathcal{H}_{\infty} \rightarrow \mathcal{H}^{\text {pre }}$ is a free resolution in the category of "matrads." Furthermore, we conjecture that the minimal resolution of $\mathcal{H}$ in the category of PROPs (and consequently, in the category of prematrads) is recovered by the universal enveloping functor $U$ discussed in Example 6.8 below, i.e., the minimal resolution of the bialgebra PROP $\mathcal{B}$ is $U(\rho): U\left(\mathcal{H}_{\infty}\right) \rightarrow U\left(\mathcal{H}^{\text {pre }}\right)=\mathcal{B}$, in which case $\mathcal{H}_{\infty}$ is the smallest extension of $\mathcal{H}^{\text {pre }}$ in the category of modules.

The precise definition of $\mathcal{H}_{\infty}$ requires more machinery.

### 6.1. Matrads Defined

Consider a family of pairs $\left(\mathbf{W}_{\alpha}, \gamma_{\alpha}\right)$, where $\mathbf{W}_{\alpha} \subset T T M$ is a telescoping submodule, and the corresponding family of telescopic extensions ( $\mathcal{W}_{\alpha}, \Upsilon_{\alpha}$ ). To each pair $\left(\mathcal{W}_{\alpha}, \Upsilon_{\alpha}\right)$ the $\Upsilon_{\alpha}$-factorizations via Definition 6.1 below determine a unique "configuration module" $\Gamma\left(\mathbf{W}_{\alpha}\right) \subseteq \mathcal{W}_{\alpha}$ with the following property: If $\mathbf{W}_{\alpha} \subseteq \mathbf{W}_{\beta}$ and $\gamma_{\mathbf{w}_{\alpha}}=\left.\gamma_{\mathbf{w}_{\beta}}\right|_{\mathbf{W}_{\alpha}}$, then $\Gamma\left(\mathbf{W}_{\alpha}\right) \subseteq \Gamma\left(\mathbf{W}_{\beta}\right)$. The local prematrad $\left(M, \gamma_{\mathbf{w}_{\alpha}}\right)$ is a "matrad" if $\mathbf{W}_{\alpha}$ is " $\Gamma$-stable," i.e., $\mathbf{W}_{\alpha}$ is the smallest telescoping submodule such that $\Gamma\left(\mathbf{W}_{\alpha}\right)=\Gamma\left(\mathbf{W}_{\beta}\right)$ whenever $\mathbf{W}_{\alpha} \subset \mathbf{W}_{\beta}$ and $\gamma_{\mathbf{w}_{\alpha}}=\left.\gamma_{\mathbf{w}_{\beta}}\right|_{\mathbf{W}_{\alpha}}$.

Matrads are intimately related to the permutahedra. Recall that each codimension $k-1$ face of $P_{m-1}$ is identified with two PLTs-an up-rooted PLT and its down-rooted mirror image-with $m$ leaves and $k \geqslant 2$ levels (see [4], [10]). Define the ( $m, 1$ )-row descent sequence of $\lambda_{m}$ to be $\mathbf{m}=(m)$. Given an up-rooted PLT $T=T^{k}$ with $k$ levels, express $T^{i}=T^{i-1} / \curlywedge_{m_{i, 1}} \cdots \curlywedge_{m_{i, r_{i}}}$ for $k \geqslant i>1$ and $T^{1}=\curlywedge_{m_{1,1}}$. Define the $i^{\text {th }}$ leaf sequence of $T$ to be the row matrix $\mathbf{m}_{i}=\left(m_{i, 1}, \ldots, m_{i, r_{i}}\right)$ and the ( $m, k$ )-row descent sequence of $T$ to be the $k$-tuple of row matrices $\left(\mathbf{m}_{1}, \ldots, \mathbf{m}_{k}\right)$. Note that the vertices of $P_{m-1}$ are identified with $(m, m-1)$-row descent sequences $\left(\mathbf{m}_{1}, \ldots, \mathbf{m}_{m-1}\right)$, where $\mathbf{m}_{i}=(1, \ldots, 2, \ldots, 1) \in \mathbb{N}^{r_{i}}$ with exactly one 2 in position $j$ for some $1 \leqslant j \leqslant r_{i}$, in which case $\mathbf{m}_{1}=(2)$. Dually, define the ( $n, 1$ )-column descent sequence of $\curlyvee^{n}$ to be $\mathbf{n}=(n)$. Given an down-rooted PLT $T=T^{l}$ with $l$ levels, express $T^{i}=\curlyvee^{n_{i, 1}} \cdots \curlyvee^{n_{i, s_{i}}}$ $/ T^{i-1}$ for $l \geqslant i>1$ and $T^{1}=r^{n_{1,1}}$. Define the $i^{t h}$ leaf sequence of $T$ to be the column
matrix $\mathbf{n}_{i}=\left(n_{i, 1}, \ldots, n_{i, s_{i}}\right)^{T}$ and the $(n, l)$-column descent sequence of $T$ to be the $l$-tuple of column matrices $\left(\mathbf{n}_{l}, \ldots, \mathbf{n}_{1}\right)$.

Given a telescoping submodule $\mathbf{W}$ and its telescopic extension $\mathcal{W}$, let $\mathcal{W}_{\text {row }}=$ $\mathcal{W} \cap \overline{\mathbf{M}}_{\text {row }}$ and $\mathcal{W}^{\text {col }}=\mathcal{W} \cap \overline{\mathbf{M}}^{\mathrm{col}}$.

Definition 6.1. Given a local prematrad $\left(M, \gamma_{\mathbf{W}}\right)$ with domain $\mathbf{W}$, let $\zeta \in M_{*, m}$ and $\xi \in M_{n, *}$ be elements with $m, n \geqslant 2$.
(i) A row factorization of $\zeta$ with respect to $\mathbf{W}$ is an $\Upsilon$-factorization $A_{1} \cdots A_{k}=$ $\zeta$ such that $A_{j} \in \mathcal{W}_{\text {row }}$ and $\operatorname{rls} A_{j} \neq \mathbf{1}$ for all $j$. The sequence $\left(\operatorname{rls} A_{1}, \ldots, \operatorname{rls} A_{k}\right)$ is the related $(m, k)$-row descent sequence of $\zeta$.
(ii) A column factorization of $\xi$ with respect to $W$ is an $\Upsilon$-factorization $B_{l} \cdots B_{1}=\xi$ such that $B_{i} \in \mathcal{W}^{\mathrm{col}}$ and $\operatorname{cls} B_{i} \neq \mathbf{1}$ for all $i$. The sequence $\left(\operatorname{cls} B_{l}\right.$, $\left.\ldots, \operatorname{cls} B_{1}\right)$ is the related $(n, l)$-column descent sequence of $\xi$.

Column and row factorizations are not unique. Note that an element $A \in M_{n, *}$ always has a trivial column factorization as the $1 \times 1$ matrix $[A]$. When matrix entries in a row factorization are pictured as graphs, terms of the row descent sequence are "lower (input) leaf sequences" of the graphs along any row, and dually for column factorizations.

Example 6.2. An $\Upsilon$-product of bisequence matrices is simultaneously a row and column factorization. For example, consider the $\Upsilon$-product

$$
C=C_{1} C_{2} C_{3}=\left[\begin{array}{c}
\theta_{2}^{1} \\
\alpha_{2}^{2} \\
\beta_{2}^{2}
\end{array}\right]\left[\begin{array}{cc}
\theta_{1}^{2} & \zeta_{2}^{2} \\
\theta_{1}^{1} & \theta_{2}^{1}
\end{array}\right]\left[\begin{array}{lll}
\theta_{1}^{2} & \xi_{2}^{2} & \theta_{1}^{2}
\end{array}\right] \in M_{5,4}
$$

As a row factorization, the $(4,3)$-row descent sequence of $C$ is

$$
\left(\mathrm{rls} C_{1}, \mathrm{rls} C_{2}, \mathrm{rls} C_{3}\right)=((2),(12),(121)),
$$

and as a column factorization, the $(5,3)$-column descent sequence of $C$ is

$$
\left(\operatorname{cls} C_{1}, \operatorname{cls} C_{2}, \operatorname{cls} C_{3}\right)=\left(\left(\begin{array}{l}
1 \\
2 \\
2
\end{array}\right),\binom{2}{1},(2)\right)
$$

((2), (12), (121))

$\left((122)^{T},(21)^{T},(2)\right)$

Given a local prematrad $\left(M, \gamma_{\mathbf{W}}\right)$ and elements $A \in M_{*, s}$ and $B \in M_{t, *}$ with $s, t \geqslant 2$, choose a row factorization $A_{1} \cdots A_{k}$ of $A$ with respect to $\mathbf{W}$ and $(s, k)$ row descent sequence $\alpha$, and a column factorization $B_{l} \cdots B_{1}$ of $B$ with respect to $\mathbf{W}$ and $(t, l)$-column descent sequence $\beta$. Then $\alpha$ identifies $A$ with an up-rooted $s$ leaf, $k$-level PLT and a codimension $k-1$ face $\hat{e}_{A}$ of $P_{s-1}$, and $\beta$ identifies $B$ with
a down-rooted $t$-leaf, $l$-level PLT and a codimension $l-1$ face ${ }_{e}{ }_{B}$ of $P_{t-1}$. Extending to Cartesian products, identify the monomials $A=A_{1} \otimes \cdots \otimes A_{q} \in\left(M_{*, s}\right)^{\otimes q}$ and $B=B_{1} \otimes \cdots \otimes B_{p} \in\left(M_{t, *}\right)^{\otimes p}$ with the product cells

$$
\hat{e}_{A}=\hat{e}_{A_{1}} \times \cdots \times \hat{e}_{A_{q}} \subset P_{s-1}^{\times q} \text { and } \stackrel{\vee}{e}_{B}=\stackrel{\vee}{e}_{B_{1}} \times \cdots \times \stackrel{\vee}{e}_{B_{p}} \subset P_{t-1}^{\times p} .
$$

Now consider the S-U diagonal $\Delta_{P}$ and recall from Section 5.2 that there is a $k$-subdivision $P_{r}^{(k)}$ of $P_{r}$ and a cellular inclusion $P_{r}^{(k)} \hookrightarrow \Delta^{(k)}\left(P_{r}\right) \subset P_{r}^{\times k+1}$ for each $k$ and $r$. Thus for each $q \geqslant 2$, the product cell $\hat{e}_{A}$ either is or is not a subcomplex of $\Delta^{(q-1)}\left(P_{s-1}\right) \subset P_{s-1}^{\times q}$, and dually for $\stackrel{\vee}{e}_{B}$. This leads to the notion of "configuration module."

Let $\mathbf{x}_{m, i}^{p}=(1, \ldots, m, \ldots, 1) \in \mathbb{N}^{1 \times p}$ with $m$ in the $i^{t h}$ position and let $\mathbf{y}_{q}^{n, j}=$ $(1, \ldots, n, \ldots, 1)^{T} \in \mathbb{N}^{q \times 1}$ with $n$ in the $j^{t h}$ position.

Definition 6.3. The (left) configuration module of a local prematrad ( $M, \gamma_{\mathbf{w}}$ ) is the $R$-module

$$
\begin{aligned}
& \Gamma\left(M, \gamma_{\mathbf{w}}\right)=M \oplus \bigoplus_{\mathbf{x}, \mathbf{y} \notin \mathbb{N} ; s, t \geqslant 1} \Gamma_{s}^{\mathbf{y}}(M) \oplus \Gamma_{\mathbf{x}}^{t}(M), \text { where } \\
& \Gamma_{s}^{\mathbf{y}}(M)=\left\{\begin{array}{cl}
\mathbf{M}_{1}^{\mathbf{y}}, & s=1 ; \mathbf{y}=\mathbf{y}_{q}^{n, j} \text { for some } n, j, q \\
\left\langle A \in \mathbf{M}_{s}^{\mathbf{y}} \mid \hat{e}_{A} \subset \Delta^{(q-1)}\left(P_{s-1}\right)\right\rangle, & s \geqslant 2 \\
0, & \text { otherwise, }
\end{array}\right. \\
& \Gamma_{\mathbf{x}}^{t}(M)=\left\{\begin{array}{cl}
\mathbf{M}_{\mathbf{x}}^{1}, & t=1 ; \mathbf{x}=\mathbf{x}_{m, i}^{p} \text { for some } m, i, p \\
\left\langle B \in \mathbf{M}_{\mathbf{x}}^{t} \mid \stackrel{\vee}{e}_{B} \subset \Delta^{(p-1)}\left(P_{t-1}\right)\right\rangle, & t \geqslant 2 \\
0, & \text { otherwise. }
\end{array}\right.
\end{aligned}
$$

Thus $\Gamma_{\mathbf{x}}^{t}(M)$ is generated by those tensor monomials $B=\beta_{x_{1}}^{t} \otimes \cdots \otimes \beta_{x_{p}}^{t} \in M_{t, x_{1}} \otimes$ $\cdots \otimes M_{t, x_{p}}$ whose tensor factor $\beta_{x_{i}}^{t}$ is identified with some factor of a product cell in $\Delta^{(p-1)}\left(P_{t-1}\right)$ corresponding to some column factorization $\beta_{x_{i}}^{t}=B_{i, l} \cdots B_{i, 1}$ with respect to $\mathbf{W}$, and dually for $\Gamma_{s}^{\mathbf{y}}(M)$.

Example 6.4. Referring to Example 3.1, let $M=M_{1,1} \oplus M_{2,2}=\left\langle\theta_{1}^{1}\right\rangle \oplus\left\langle\theta_{2}^{2}\right\rangle$, and consider the local prematrad $\left(M, \gamma_{\mathrm{v}}\right)$. Note that the action of $\gamma_{\mathrm{v}}$ is trivial modulo unit (e.g., $\mathbf{M}_{2}^{2} \cdot \mathbf{M}_{11}^{1}=\mathbf{M}_{2}^{2}$ and $\mathbf{M}_{2}^{22} \cdot \mathbf{M}_{22}^{2} \subseteq \mathbf{M}_{4}^{4}=0$ ). Then

$$
\Gamma_{*}^{1}(M) \approx \Gamma_{1}^{*}(M) \approx T^{+}\left(M_{1,1}\right)
$$

Since $A=\left(\theta_{2}^{2}\right)^{\otimes q}$ can be thought of as an element of either $\mathbf{M}_{2 \cdots 2}^{2}$ or $\mathbf{M}_{2}^{2 \cdots 2}$, we have either $\hat{e}_{A}=\Delta^{(q-1)}\left(P_{1}\right)=P_{1}^{\times q}$ or $\stackrel{\vee}{e}_{A}=\Delta^{(q-1)}\left(P_{1}\right)=P_{1}^{\times q}$ so that

$$
\Gamma_{*}^{2}(M) \approx \Gamma_{2}^{*}(M) \approx T^{+}\left(M_{2,2}\right)
$$

Thus

$$
\Gamma\left(M, \gamma_{\mathbf{v}}\right)=\mathbf{V}
$$

Since $r=1$ is the only case in which the equality $\Delta^{(k)}\left(P_{r}\right)=P_{r}^{\times k+1}$ holds for each $k$, it follows immediately that if $A \in M_{n, m}$ is $\gamma_{\mathrm{w}}$-indecomposable (in which case its row and column factorizations with respect to $\mathbf{W}$ are trivial) and $\hat{e}_{A} \times \cdots \times \hat{e}_{A}$ $=e^{m-2} \times \cdots \times e^{m-2}$ is a subcomplex of $\Delta^{(n-1)}\left(P_{m-1}\right)$, then either $m=2$ and $n$ is arbitrary or $m>2$ and $n=1$; dually, if $e_{A} \times \cdots \times e_{A}=e^{n-2} \times \cdots \times e^{n-2}$ is a subcomplex of $\Delta^{(m-1)}\left(P_{n-1}\right)$, then either $m$ is arbitrary and $n=2$ or $m=1$ and $n>2$. Consequently,

$$
\bigoplus_{\mathbf{x}} \Gamma_{\mathbf{x}}^{2}(M) \approx T^{+}\left(M_{2, *}\right) \text { and } \bigoplus_{\mathbf{y}} \Gamma_{2}^{\mathbf{y}}(M) \approx T^{+}\left(M_{*, 2}\right)
$$

Furthermore, if $m+n \geqslant 4,(m, n) \neq(2,2)$, and $A^{\otimes r} \in \Gamma\left(M, \gamma_{\mathbf{w}}\right)$, then $r=1$, and the inclusion $\Gamma_{s}^{\mathbf{y}}(M) \subseteq \mathbf{M}_{s}^{\mathbf{y}}$ is proper whenever $s \geqslant 3, \mathbf{y} \in \mathbb{N}^{q \times 1}$ with $q \geqslant 2$, and $M_{y_{j}, s}$ contains a $\gamma_{\mathbf{W}}$-indecomposable element for each $1 \leqslant j \leqslant q$, and dually for $\Gamma_{\mathbf{x}}^{t}(M) \subseteq$ $\mathrm{M}_{\mathrm{x}}^{t}$.

We are ready to define the notion of a matrad.
Definition 6.5. A local prematrad $\left(M, \gamma_{\mathbf{w}}, \eta\right)$ is a (left) matrad if

$$
\Gamma_{p}^{\mathbf{y}}\left(M, \gamma_{\mathbf{w}}\right) \otimes \Gamma_{\mathbf{x}}^{q}\left(M, \gamma_{\mathbf{w}}\right)=\mathbf{W}_{p}^{\mathbf{y}} \otimes \mathbf{W}_{\mathbf{x}}^{q}
$$

for all $p, q \geqslant 2$. A morphism of matrads is a map of underlying local prematrads.
Example 6.6 (The Bialgebra Matrad $\mathcal{H}$ ). The bialgebra prematrad $\mathcal{H}^{\text {pre }}$ satisfies $\Gamma_{p}^{\mathbf{y}}(M) \otimes \Gamma_{\mathbf{x}}^{q}(M)=\mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q}$ for $p, q \geqslant 2$. Hence $\mathcal{H}^{\text {pre }}$ is also a matrad, called the bialgebra matrad and henceforth denoted by $\mathcal{H}$.

Example 6.7. Continuing Example 4.21, the inclusions $\left(M_{1, *}, \gamma_{\mathrm{M}_{4}^{1}}\right) \subset\left(M, \gamma_{\mathrm{M}_{4}^{1}}\right)$ and $\left(M_{*, 1}, \gamma_{\mathbf{M}_{1}^{*}}\right) \subset\left(M, \gamma_{\mathbf{M}_{1}^{*}}\right)$ are inclusions of matrads since $\Gamma_{p}^{\mathbf{y}}\left(M, \gamma_{\mathbf{M}_{1}^{*}}^{*}\right) \otimes \Gamma_{\mathbf{x}}^{q}\left(M, \gamma_{\mathbf{M}_{*}^{1}}\right)=$ $\mathbf{M}_{p}^{\mathbf{y}} \otimes \mathbf{M}_{\mathbf{x}}^{q}=0$ for $p, q \geqslant 2$. In particular, when $M=F^{\text {pre }}(\Theta)$ and $\theta_{m}^{n} \neq 0$ for all $m, n \geqslant 1$, the free operad $\left(\mathcal{A}_{\infty}, \gamma_{\mathbf{M}_{*}^{\frac{1}{*}}}\right)$ embeds in $\left(F^{\text {pre }}(\Theta), \gamma_{\mathrm{M}_{\frac{1}{1}}}\right)$ as a submatrad (cf. Example 4.14 and Definition 6.9 below).

Example 6.8 (The Universal Enveloping Functor $U$ ). The universal enveloping PROP $U$ discussed in Example 4.12 induces the universal enveloping functor $U$ from the category of matrads to the category of PROPs. Given a matrad $\left(M, \gamma_{\mathbf{w}}\right)$, let $F P(M)$ be the free PROP generated by $M$ and let $J$ be the two-sided ideal generated by the elements $\bigoplus_{\mathbf{x} \times \mathbf{y}}\left(\gamma_{\mathbf{w}}-\gamma_{F P}\right)\left(\Gamma_{p}^{\mathbf{y}}(M) \otimes \Gamma_{\mathbf{x}}^{q}(M)\right)$. Then $U(M)=F P(M) / J$.

### 6.2. Free Matrads

Recall that the domain of the free prematrad $\left(M=F^{\text {pre }}(\Theta), \gamma, \eta\right)$ generated by $\Theta=\left\langle\theta_{m}^{n}\right\rangle_{m, n \geqslant 1}$ is $\mathbf{V}=M \oplus \underset{\mathbf{x}, \mathbf{y} \notin \mathbb{N} ; s, t \in \mathbb{N}}{\oplus} \mathbf{M}_{s}^{\mathbf{y}} \oplus \mathbf{M}_{\mathbf{x}}^{t}$ whose submodules $M, \mathbf{M}_{\mathbf{x}}^{1}$, and $\mathbf{M}_{1}^{\mathbf{y}}$ are contained in the configuration module $\Gamma(M)$. As above, the symbol "." denotes the $\gamma$ product.

Definition 6.9. Let $\left(M=F^{\text {pre }}(\Theta), \gamma, \eta\right)$ be the free prematrad generated by $\Theta=$ $\left\langle\theta_{m}^{n}\right\rangle_{m, n \geqslant 1}$, let $F(\Theta)=\Gamma(M) \cdot \Gamma(M)$, and let $\gamma_{F(\Theta)}=\left.\gamma\right|_{\Gamma(M) \otimes \Gamma(M)}$. The free matrad generated by $\Theta$ is the triple $\left(F(\Theta), \gamma_{F(\Theta)}, \eta\right)$.

Remark 6.10. Let $\omega=\sum \theta_{m}^{n}$ and consider the biderivative $d_{\omega}$. Then $F(\Theta)$ is generated by the components of $d_{\omega} \odot d_{\omega}$ in $F^{\text {pre }}(\Theta)$ (the admissible fractions). Thus $\Gamma\left(F(\Theta), \gamma_{F(\Theta)}\right) \backslash F(\Theta)=\Gamma\left(F^{\text {pre }}(\Theta), \gamma_{\mathbf{V}}\right) \backslash F^{\mathrm{pre}}(\Theta)$ (cf. Proposition 6.14).

Let $\beta \in \mathcal{B}^{\text {pre }}$. In Subsection 4.3 we constructed the $r$-level tree $\Psi(\beta)$ whose leaves are balanced $\Theta$-factorizations; the set $\mathcal{C}^{\text {pre }}=\left\{\Psi(\beta) \mid \beta \in \mathcal{B}^{\text {pre }}\right\}$ indexes the set $G^{\text {pre }} / \sim$ of module generators of the free prematrad $F^{\text {pre }}(\Theta)$. Let $\mathfrak{G}=F(\Theta) \cap G^{\text {pre }} / \sim$ and let $\mathcal{B}=\phi(\mathfrak{G})$. Then

$$
\mathcal{C}=\{\Psi(\beta)) \mid \beta \in \mathcal{B}\}
$$

indexes the set $\mathfrak{G}$ of module generators of $F(\Theta)$.
To establish the relationship between elements of $\mathfrak{G}$ and cells of $K K_{n, m}$, let $\beta=A_{s} \cdots A_{1} \in \mathcal{B}_{n, m}^{\text {pre }}$ and observe that $\beta \in \mathcal{B}_{n, m}$ if and only if the tensor monomials along each row and column of $A_{k}$ lie in $\Gamma\left(F^{\text {pre }}(\Theta)\right)$ for all $k$ (see (23) below). Let

$$
\mathcal{C}_{n, m}^{\prime \prime}=\left\{\Psi(\beta) \mid \beta=A_{s} \cdots A_{1} \in \mathcal{B}_{n, m} \text { and either } A_{1} \text { or } A_{s} \text { is a } 1 \times 1\right\}
$$

then in particular, $\mathcal{C}_{1, m}^{\prime \prime}=\mathcal{C}_{1, m}$ and $\mathcal{C}_{n, 1}^{\prime \prime}=\mathcal{C}_{n, 1}$. Let $\mathcal{C}_{n, m}^{\prime}=\mathcal{C}_{n, m} \backslash \mathcal{C}_{n, m}^{\prime \prime}$; then $\mathcal{C}_{n, m}=\mathcal{C}_{n, m}^{\prime} \sqcup \mathcal{C}_{n, m}^{\prime \prime}$ for each $m, n \geqslant 1$. Elements of $\mathcal{C}^{\prime}$ are defined in terms of $\Delta_{P}$; elements of $\mathcal{C}^{\prime \prime}$ are independent of $\Delta_{P}$.

Define the dimension of $\theta_{1}^{1}=\mathbf{1}$ to be zero and the dimension of $\theta_{m}^{n}$ to be $m+$ $n-3$; if $A \in \mathfrak{G}$, then the dimension of $A$, denoted by $|A|$, is the sum of the dimensions of the matrix entries in any representative monomial in $G$, and in particular, in its balanced factorization in $\mathcal{B}$. Clearly, given $\mathbf{x} \times \mathbf{y} \in \mathbb{N}^{1 \times p} \times \mathbb{N}^{q \times 1}$, the set $\left\{|A| \mid A \in \mathbf{G}_{\mathbf{x}}^{\mathbf{y}}\right\}$ is bounded and, consequently, has a maximal element. For example, if $A$ is a monomial in $\Gamma_{s}^{\mathbf{y}}\left(F(\Theta)\right.$ ) with $s \geqslant 2$ and $\hat{e}_{A}$ is the corresponding subcomplex of $\Delta^{(q-1)}\left(P_{s-1}\right)$, then $|A|=\left|\hat{e}_{A}\right|+|\mathbf{y}|-q$; and dually, if $B$ is a monomial in $\Gamma_{\mathbf{x}}^{t}(F(\Theta))$ with $t \geqslant 2$ and $\check{e}_{B}$ is the corresponding subcomplex of $\Delta^{(p-1)}\left(P_{t-1}\right)$, then $|B|=\left|\stackrel{\vee}{e_{B}}\right|+|\mathbf{x}|-p$. Consequently, $\max \left\{|A| \mid A \in \Gamma_{s}^{\mathbf{y}}(F(\Theta))\right\}=|\mathbf{y}|+s-q-2$ and $\max \left\{|B| \mid B \in \Gamma_{\mathbf{x}}^{t}(F(\Theta))\right\}=|\mathbf{x}|+t-p-2$. In particular, if $A \in \mathfrak{G}_{n+1, m+1}$ has balanced factorization $\beta=A_{s} \cdots A_{1}, \quad 1 \leqslant s \leqslant m+n$, then $\operatorname{codim} A \geqslant s-1$ and $\operatorname{codim} A=s-1$ if and only if the dimensions of each bisequence matrix $A_{k}$ is maximal (see (28) below).

Given $m+n \geqslant 3$ and $\mathbf{x} \times \mathbf{y} \in \mathbb{N}^{1 \times p} \times \mathbb{N}^{q \times 1}$ such that $|\mathbf{x}|=m$ and $|\mathbf{y}|=n$, define the codimension 1 face $e_{(\mathbf{y}, \mathbf{x})} \subset P_{m+n-2}$ as follows: If $|\mathbf{x}|=m>p \geqslant 2$, let $A_{\mathbf{x}} \mid B_{\mathbf{x}}$ be the codimension 1 face of $P_{m-1}$ with leaf sequence $\mathbf{x}$; dually, if $|\mathbf{y}|=n>q \geqslant 2$, let $A_{\mathbf{y}} \mid B_{\mathbf{y}}$ be the codimension 1 face of $P_{n-1}$ with leaf sequence $\mathbf{y}$. If $A=\left\{a_{1}, \ldots, a_{r}\right\} \subset \mathbb{Z}$ and $z \in \mathbb{Z}$, define $-A=\left\{-a_{1}, \ldots,-a_{n}\right\}$ and $A+z=\left\{a_{1}+z, \ldots, a_{r}+z\right\}$; then set

$$
\begin{aligned}
& A_{1}=\left\{\begin{array}{cl}
\frac{m-1,}{} & \text { if } \mathbf{x}=\mathbf{1}^{m}, m \geqslant 1 \\
\varnothing, & \text { if } \mathbf{x}=m \geqslant 2 \\
-A_{\mathbf{x}}+m, & \text { otherwise, }
\end{array} \quad A_{2}=\left\{\begin{array}{cl}
\varnothing, & \text { if } \mathbf{y}=\mathbf{1}^{n}, n \geqslant 1 \\
\frac{n-1}{A_{\mathbf{y}},} & \text { if } \mathbf{y}=n \geqslant 2 \\
\text { otherwise },
\end{array}\right.\right. \\
& B_{1}=\left\{\begin{array}{cl}
\varnothing, & \text { if } \mathbf{x}=\mathbf{1}^{m}, m \geqslant 1 \\
\frac{m-1,}{-B_{\mathbf{x}}+m,} & \text { if } \mathbf{x}=m \geqslant 2
\end{array} \quad\right. \text { otherwise, }
\end{aligned} \quad B_{2}=\left\{\begin{array}{cl}
\frac{n-1}{\varnothing,} & \text { if } \mathbf{y}=\mathbf{1}^{n}, n \geqslant 1 \\
\varnothing, & \text { if } \mathbf{y}=n \geqslant 2 \\
B_{\mathbf{y}}, & \text { otherwise },
\end{array}\right.
$$

and define

$$
\begin{equation*}
e_{(\mathbf{y}, \mathbf{x})}=A_{1} \cup\left(A_{2}+m-1\right) \mid B_{1} \cup\left(B_{2}+m-1\right) . \tag{13}
\end{equation*}
$$

For example, $e_{\left(\mathbf{1}^{n}, \mathbf{1}^{m}\right)}=\underline{m-1}\left|(\underline{n-1}+m-1), \quad e_{(n, m)}=(\underline{n-1}+m-1)\right| \underline{m-1}$, and $e_{((21),(21))}=13 \mid 24$.

Example 6.11 (The $A_{\infty}$-bialgebra Matrad $\mathcal{H}_{\infty}$ ). Let $\Theta=\left\langle\theta_{m}^{n} \neq 0 \mid \theta_{1}^{1}=\mathbf{1}\right\rangle_{m, n \geqslant 1}$. We say that $\beta \in \mathcal{B}_{n, m}$ has word length 2 if $\beta=C_{2} C_{1}$ for some $C_{2} \times C_{1} \in \mathbf{G}_{p}^{\mathbf{y}} \times \mathbf{G}_{\mathbf{x}}^{q}$, where $\mathbf{x} \times \mathbf{y} \in \mathbb{N}^{1 \times p} \times \mathbb{N}^{q \times 1},|\mathbf{x}|=m$, and $|\mathbf{y}|=n$. Let

$$
\mathcal{A}_{p}^{\mathbf{y}} \times \mathcal{B}_{\mathbf{x}}^{q}=\left\{\Psi(\beta) \mid \beta \in \mathcal{B}_{n, m} \text { has word length } 2\right\} .
$$

Denote the corresponding bases of $\Gamma_{\mathbf{x}}^{q}(F(\Theta))$ and $\Gamma_{p}^{\mathbf{y}}(F(\Theta))$ by $\left\{\left(B_{\mathbf{x}}^{q}\right)_{\beta}\right\}_{\beta \in \mathcal{B}_{\mathbf{x}}^{q}}$ and $\left\{\left(A_{p}^{\mathbf{y}}\right)_{\alpha}\right\}_{\alpha \in \mathcal{A}_{p}^{\mathbf{y}}}$, respectively. Then $A_{i}^{j}=B_{i}^{j}=\theta_{i}^{j}$ with $\left|\theta_{i}^{j}\right|=i+j-3 ; B_{\mathbf{x}}^{1}=\theta_{m}^{p, i}$ with $\mathbf{x}=\mathbf{x}_{m}^{p, i}$ and $\left|B_{\mathbf{x}}^{1}\right|=m-2$, and $A_{1}^{\mathbf{y}}=\theta_{q, j}^{n}$ with $\mathbf{y}=\mathbf{y}_{q, j}^{n}$ and $\left|A_{1}^{\mathbf{y}}\right|=n-2$ (cf. Example 4.14). In general, for $p, q \geqslant 2,\left|\left(B_{\mathbf{x}}^{q}\right)_{\beta}\right|=|\mathbf{x}|+q-p-2$ and $\left|\left(A_{p}^{\mathbf{y}}\right)_{\alpha}\right|=|\mathbf{y}|+p-$ $q-2$. Then each $\hat{e}_{A_{\alpha}}$ is a subcomplex of $\Delta^{(q-1)}\left(P_{p-1}\right)$ with the associated sign $(-1)^{\epsilon_{\alpha}}$ and each $\check{e}_{B_{\beta}}$ is a subcomplex of $\Delta^{(p-1)}\left(P_{q-1}\right)$ with the associated sign $(-1)^{\epsilon_{\beta}}$. Define a differential $\partial: F(\Theta) \rightarrow F(\Theta)$ of degree -1 as follows: Define $\partial$ on generators by

$$
\begin{equation*}
\partial\left(\theta_{m}^{n}\right)=\sum_{(\alpha, \beta) \in \mathcal{A B}_{m, n}}(-1)^{\epsilon+\epsilon_{\alpha}+\epsilon_{\beta}} \gamma\left[\left(A_{p}^{\mathbf{y}}\right)_{\alpha} ;\left(B_{\mathbf{x}}^{q}\right)_{\beta}\right], \tag{14}
\end{equation*}
$$

where $(-1)^{\epsilon}$ is the standard sign of $e_{(\mathbf{y}, \mathbf{x})} \subset P_{m+n-2}$. Extend $\partial$ as a derivation of $\gamma$; then $\partial^{2}=0$ follows from the associativity of $\gamma$. The DG matrad $(F(\Theta), \partial)$, denoted by $\mathcal{H}_{\infty}$ and called the $A_{\infty}$-bialgebra matrad, is realized by the biassociahedra $\left\{K K_{n, m} \leftrightarrow \theta_{m}^{n}\right\}$ (see Theorem 9.13 below). One recovers $\mathcal{A}_{\infty}$ by restricting $\partial$ to $\left(\mathcal{H}_{\infty}\right)_{1, *}$ or $\left(\mathcal{H}_{\infty}\right)_{*, 1}$. Note that $\epsilon=i(m-1)$ in (14) gives the sign of the cell $e_{\left(\mathbf{y}_{p, i}^{m}, \mathbf{1}\right)}=e_{\left(\mathbf{1}, \mathbf{x}_{m}^{p, i}\right)} \subset P_{m+p-2}$ (see [10]). This simplifies the standard sign in the differential on $\mathcal{A}_{\infty}[\mathbf{6}]$.

Example 6.12. For $\mathbf{x}=(2,1)$ and $\mathbf{y}=(1,1,1)^{T}$, we have $\mathcal{A}_{2}^{111}=\{\alpha\}$ and $\mathcal{B}_{21}^{3}=\left\{\beta_{1}\right.$, $\left.\beta_{2}, \beta_{3}\right\}$. The corresponding bases are

$$
\left.\begin{array}{l}
A_{\alpha}=\left[\begin{array}{c}
\theta_{2}^{1} \\
\theta_{2}^{1} \\
\theta_{2}^{1}
\end{array}\right] \text { and } B_{\beta_{1}}=\left[\theta_{2}^{3}\right. \\
\left.B_{\beta_{2}}=\left[\begin{array}{c}
\theta_{1}^{1} \\
\theta_{1}^{2}
\end{array}\right] \theta_{1}^{2}\right], \\
\left.\left[\begin{array}{c}
\theta_{2}^{2} \\
\theta_{2}^{1}
\end{array}\right]\left[\theta_{1}^{2} \theta_{1}^{2}\right] \quad \theta_{1}^{3}\right], B_{\beta_{3}}=\left[\left[\begin{array}{c}
\theta_{1}^{2} \\
\theta_{1}^{1}
\end{array}\right] \theta_{2}^{2}\right. \\
\theta_{1}^{3}
\end{array}\right] . .
$$

Thus, $\partial\left(\theta_{3}^{3}\right)=-\gamma\left(A_{\alpha} ; B_{\beta_{1}}+B_{\beta_{2}}+B_{\beta_{3}}\right)+\cdots$ (see Example 9.14).

### 6.3. The Biderivative

In [11] we used the canonical prematrad structure $\gamma$ on the universal PROP $U_{A}=\operatorname{End}(T A)$ to define the biderivative operator. By replacing $U_{A}$ with an arbitrary prematrad $(M, \gamma)$ we obtain the general biderivative operator $B d_{\gamma}: \mathbf{M} \rightarrow \mathbf{M}$ having the property $B d_{\gamma} \circ B d_{\gamma}=B d_{\gamma}$. An element $A \in \mathbf{M}$ is a $\gamma$-biderivative if $A=B d_{\gamma}(A)$. Note that $B d_{\gamma}(\mathbf{M}) \subseteq(\Gamma(M), \gamma)$; when $M$ is generated by singletons in each bidegree,
the image $B d_{\gamma}(\mathbf{M})$ is the module of fixed points of $B d_{\gamma}$ and gives rise to an algorithmic construction of an additive basis for the $A_{\infty}$-bialgebra matrad $\mathcal{H}_{\infty}$. More precisely:

Proposition 6.13. Let $(M, \gamma)$ be a prematrad generated by $\Theta=\left\{\theta_{m}^{n} \mid \theta_{1}^{1}=\mathbf{1}\right\}_{m, n \geqslant 1}$, and let $B d_{\gamma}: \mathbf{M} \rightarrow \mathbf{M}$ denote the associated biderivative operator. Then
(i) $B d_{\gamma}(\mathbf{M}) \subseteq \Gamma(M, \gamma)$ and $B d_{\gamma} \circ B d_{\gamma}=B d_{\gamma}$.
(ii) Each element $\theta \in \Theta$ has a unique $\gamma$-biderivative $d_{\theta}^{\gamma} \in \mathbf{M}$.
(iii) $\Gamma(M, \gamma)=\left\langle d_{\theta}^{\gamma}\right\rangle$.

Thus the $\gamma$-biderivative can be viewed as a non-linear map $d_{\bullet}^{\gamma}: M \rightarrow \mathbf{M}$. When $M=$ $\operatorname{End}(T A)$ we omit the symbol $\gamma$ and denote the biderivative of $\theta$ by $d_{\theta}$ as in [11].

In particular, the modules $\left\langle B d_{\gamma}\left(M_{*, 2}\right)\right\rangle \subseteq T^{+}\left(M_{*, 2}\right)$ and $\left\langle B d_{\gamma}\left(M_{2, *}\right)\right\rangle \subseteq T^{+}\left(M_{2, *}\right)$ are spanned by symmetric tensors (cf. Example 6.4); furthermore, $B d_{\gamma}\left(M_{n, m}\right)=$ $M_{n, m}$ for $m, n>2$.

Finally, the algorithm that produces $d_{\theta}^{\gamma}$ for $(M, \gamma)=\left(F^{\text {pre }}(\Theta), \gamma\right)$ simultaneously produces an additive basis for $\mathcal{H}_{\infty}$.

Proposition 6.14. Let $\Theta=\left\langle\theta_{m}^{n} \neq 0 \mid \theta_{1}^{1}=\mathbf{1}\right\rangle_{m, n \geqslant 1}$ as in Example 6.11. Elements of the bases $\left\{\left(A_{p}^{\mathbf{y}}\right)_{\alpha}\right\}_{\alpha \in \mathcal{A}_{p}^{\mathbf{y}}}$ and $\left\{\left(B_{\mathbf{x}}^{q}\right)_{\beta}\right\}_{\beta \in \mathcal{B}_{\mathbf{x}}^{q}}$ are exactly the components of $d_{\theta}^{\gamma}$ in $\Gamma_{p}^{\mathbf{y}}(F(\Theta), \gamma)$ and $\Gamma_{\mathbf{x}}^{q}(F(\Theta), \gamma)$ with degrees $|\mathbf{y}|+p-q-2$ and $|\mathbf{x}|+q-p-2$, respectively. Thus

$$
\partial\left(\theta_{m}^{n}\right)=\sum_{\substack{|\mathbf{x}|=m ;|\mathbf{y}|=n \\ A \times B \in\left(d_{\theta}^{\gamma}\right)_{p}^{\mathbf{y}} \times\left(d_{\theta}^{\gamma}\right)_{\mathbf{x}}^{q}}} \gamma(A ; B)
$$

Proof. The proof follows from the definition of $d_{\theta}^{\gamma}$ and is straightforward.
6.3.1. The ©-Product

Given a prematrad $(M, \gamma)$, define a (non-bilinear) operation

$$
\begin{equation*}
\bigcirc: M \times M \xrightarrow{d \cdot \times d} \mathbf{~} \mathbf{M} \times \mathbf{M} \xrightarrow{\Upsilon} \mathbf{M} \xrightarrow{\text { proj }} M \tag{15}
\end{equation*}
$$

where proj is the canonical projection. The following facts are now obvious:
Proposition 6.15. The © operation acts bilinearly on $M_{*, 1}$ and $M_{1, *}$. In fact, when $M=E n d(T H)$, the © operation coincides with Gerstenhaber's $\circ_{i}$-operation on $M_{1 . *}$ (see [2]) and dually on $M_{*, 1}$.

Remark 6.16. The bilinear part of the © operation, i.e., its restriction to either $M_{*, 1}$ or $M_{1, *}$, is completely determined by the associahedra $K=\sqcup K_{n}$ (rather than permutahedra) and induces the cellular projection $\vartheta_{0}: P_{n} \rightarrow K_{n+1}$ due to A. Tonks [15].

## 7. The Posets $\mathcal{P P}$ and $\mathcal{K} \mathcal{K}$

In this section we construct a poset $\mathcal{P \mathcal { P }}$ and an appropriate quotient poset $\mathcal{K} \mathcal{K}$. The elements of $\mathcal{K} \mathcal{K}$ correspond with the 0 -dimensional module generators of the free matrad $\mathcal{H}_{\infty}$. The geometric realization of $\mathcal{K} \mathcal{K}$, constructed in Section 8, is the disjoint
union of biassociahedra $K K=\left\{K K_{n, m}\right\}_{m, n \geqslant 1}$ whose cellular chains are identified with $\mathcal{H}_{\infty}$.

Let $\mathcal{V}_{n}$ denote the set of vertices of $P_{n}$ and identify $\mathcal{V}_{n}$ with the set $S_{n}$ of permutations of $\underline{n}=\{1,2, \ldots, n\}$ via the standard bijection $\mathcal{V}_{n} \leftrightarrow S_{n}$. The Bruhat partial ordering on $S_{n}$ generated by the relation $a_{1}|\cdots| a_{n}<a_{1}|\cdots| a_{i+1}\left|a_{i}\right| \cdots \mid a_{n}$ if and only if $a_{i}<a_{i+1}$ imposes a poset structure on $\mathcal{V}_{n}$. For $n \geqslant 1$, set $\mathcal{P} \mathcal{P}_{n, 0}=\mathcal{P} \mathcal{P}_{0, n}=\mathcal{V}_{n}$ and define the geometric realization $P P_{n, 0}=\left|\mathcal{P} \mathcal{P}_{n, 0}\right|=\left|\mathcal{P} \mathcal{P}_{0, n}\right|=P P_{0, n}$ to be the permutahedron $P_{n}$. Then $K K_{n+1,1}=\left|\mathcal{K} \mathcal{K}_{n+1,1}\right|=\left|\mathcal{K} \mathcal{K}_{1, n+1}\right|=K K_{1, n+1}$ is the Stasheff associahedron $K_{n+1}$ (see $\left.[\mathbf{1 3}],[\mathbf{1 4}],[\mathbf{1 0}]\right)$. In the discussion that follows, we construct the posets $\mathcal{P} \mathcal{P}_{n, m}$ and $\mathcal{K} \mathcal{K}_{n+1, m+1}$ and their geometric realizations $P P_{n, m}$ and $K K_{n+1, m+1}$ for all $m, n \geqslant 1$.

Denote the sets of up-rooted and down-rooted binary trees with $n+1$ leaves and $n$ levels by $\wedge_{n}$ and $\vee_{n}$, respectively; then each vertex of $P_{n}$ is indexed by two binary PLTs, one the reflection of the other. These indexing sets have a poset structure induced by the standard bijections $\hat{\ell}: \wedge_{n} \rightarrow \mathcal{V}_{n}$ and $\check{\ell}: \vee_{n} \rightarrow \mathcal{V}_{n}$, and the products $\wedge_{m}^{\times n}, \vee_{n}^{\times m}$, and $\wedge_{m}^{\times n} \times \vee_{n} \times m$ are posets with respect to lexicographic ordering. Now consider the subcomplexes $\Delta^{(n)}\left(P_{m}\right) \subseteq P_{m}^{\times n+1}$ and $\Delta^{(m)}\left(P_{n}\right) \subseteq P_{n}^{\times m+1}$ with faces of $P_{m}$ and $P_{n}$ indexed by up-rooted and down-rooted PLTs, respectively. Then the 0 -skeletons $X_{m}^{n+1} \subseteq \Delta^{(n)}\left(P_{m}\right)$ and $Y_{n}^{m+1} \subseteq \Delta^{(m)}\left(P_{n}\right)$ are subposets of $\wedge_{m}^{\times n+1}$ and $\vee_{n}^{\times m+1}$ and there is the inclusion of posets

$$
X_{m}^{n+1} \times Y_{n}^{m+1} \hookrightarrow \wedge_{m}^{\times n+1} \times \vee_{n}^{\times m+1}
$$

Express $x \in \wedge_{m}^{\times n}$ as an $n \times 1$ column matrix of up-rooted binary trees and replace $x$ with its (unique) BTP $\Upsilon$-factorization $x_{1} \cdots x_{m} \in \overline{\mathbf{M}}$, where $x_{i}$ is an $n \times i$ matrix over $\{\mathbf{1}, \curlywedge\}$ with $\curlywedge$ appearing in each row exactly once. Dually, express $y \in \vee_{n}^{\times m}$ as an $1 \times m$ row matrix of down-rooted binary trees and replace $y$ with its (unique) BTP factorization as a $\Upsilon$-product $y_{n} \cdots y_{1} \in \overline{\mathbf{M}}$, where $y_{j}$ is an $j \times m$ matrix over $\{\mathbf{1}, \curlyvee\}$ with $\curlyvee$ appearing in each column exactly once.

Example 7.1. Whereas the product $\Delta^{(1)}\left(P_{1}\right)=P_{1}^{\times 2}$ can be thought of as either $\lambda \times \lambda$ or $\curlyvee \times \curlyvee$, we have

$$
X_{1}^{2}=\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right] \text { and } Y_{1}^{2}=[\curlyvee \curlyvee] \quad \text { so that } X_{1}^{2} \times Y_{1}^{2}=\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right][\curlyvee \curlyvee]
$$

The poset of vertices in $\Delta^{(1)}\left(P_{2}\right) \subset P_{2}^{\times 2}$ expresses the following products of permutations and matrix sequences:

$$
\begin{aligned}
a|b \times c| d & : \\
X_{2}^{2} & :\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & 1 \\
\curlywedge & 1
\end{array}\right]<\left[\begin{array}{l}
\curlywedge \\
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1} \\
\mathbf{1} & \curlywedge
\end{array}\right]
\end{aligned}<\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\mathbf{1} & \curlywedge \\
\mathbf{1} & \curlywedge
\end{array}\right]
$$

Furthermore, thinking of the product $\Delta^{(2)}\left(P_{1}\right)=P_{1}^{\times 3}$ as $\curlyvee \times \curlyvee \times \curlyvee$, we have
$Y_{1}^{3}=\left[\begin{array}{lll}\curlyvee & \curlyvee & \curlyvee\end{array}\right]$; consequently $X_{2}^{2} \times Y_{1}^{3}=$

$$
\left\{\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1} \\
\curlywedge & \mathbf{1}
\end{array}\right]\left[\begin{array}{rl} 
& \curlyvee \\
\jmath
\end{array}\right]<\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1} \\
\mathbf{1} & \curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlyvee & \curlyvee \\
\curlyvee
\end{array}\right]<\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\mathbf{1} & \curlywedge \\
\mathbf{1} & \curlywedge
\end{array}\right]\left[\begin{array}{lll}
\curlyvee & \curlyvee & \curlyvee
\end{array}\right]\right\} .
$$

Definition 7.2. Let $A=\left[a_{i j}\right]$ be an $(n+1) \times m$ matrix over $\{\mathbf{1}, \curlywedge\}$, each row of which contains the entry $\lambda$ exactly once. Let $B=\left[b_{i j}\right]$ be an $n \times(m+1)$ matrix over $\{\mathbf{1}, \curlyvee\}$, each column of which contains the entry $\curlyvee$ exactly once. Then $(A, B)$ is an $(i, j)$-edge pair if
(i) $A \otimes B$ is a BTP,
(ii) $a_{i j}=a_{i+1, j}=\curlywedge$ and $b_{i j}=b_{i, j+1}=\curlyvee$.

For $u=A_{1} \cdots A_{m} B_{n} \cdots B_{1} \in X_{m}^{n+1} \times Y_{n}^{m+1}$, the only possible edge pair in $u$ is $\left(A_{m}, B_{n}\right)$. In $X_{2}^{3} \times Y_{2}^{3}$, for example, the respective matrix sequences
do and do not contain an edge pair.
Definition 7.3. Let $Q$ be a poset and let $x_{1} \leqslant x_{2} \in Q$. The pair ( $x_{1}, x_{2}$ ) is an edge of $Q$ if $x \in Q$ and $x_{1} \leqslant x \leqslant x_{2}$ implies $x=x_{1}$ or $x=x_{2}$.

Edges of $X_{m}^{n+1} \times Y_{n}^{m+1}$ correspond to 1-dimensional elements of $\mathcal{H}_{\infty}$ generated by $\left\{\mathbf{1}, \theta_{2}^{1}, \theta_{1}^{2}, \quad \theta_{3}^{1}, \theta_{1}^{3}\right\} ; 1$-dimensional elements of $\mathcal{H}_{\infty}$ generated by $\left\{\mathbf{1}, \theta_{2}^{1}, \theta_{1}^{2}, \theta_{2}^{2}\right\}$ correspond to edges of a poset $Z_{n, m}$ related to but disjoint from $X_{m}^{n+1} \times Y_{n}^{m+1}$, which we now define.

Let $A^{i *}$ and $B^{* j}$ denote the matrices obtained by deleting the $i^{\text {th }}$ row of $A$ and the $j^{\text {th }}$ column of $B$.

Definition 7.4. Let $c=C_{1} \cdots C_{r}$ be a string of matrices in which $\left(C_{k}, C_{k+1}\right)$ is an $(i, j)$-edge pair for some $k \leqslant r-1$, and suppose that some association of $C_{1} \cdots\left(C_{k} C_{k+1}\right) \cdots C_{r}$ defines a sequence of BTPs. The $(i, j)$-transposition of $c$ in position $k$ is the string

$$
\mathcal{T}_{i j}^{k}(c)=C_{1} \cdots C_{k+1}^{* j} C_{k}^{i *} \cdots C_{r}
$$

The symbol $\mathcal{T}_{i j}^{k}(c)$ implies that the action of $\mathcal{T}_{i j}^{k}$ on $c$ is defined.
Note that if $\mathcal{T}_{i j}^{k}$ acts on $u=A_{1} \cdots A_{m} B_{n} \cdots B_{1} \in X_{m}^{n+1} \times Y_{n}^{m+1}$, then $k=m$ and the potential edge pairs of consecutive matrices in

$$
\mathcal{T}_{i j}^{m}(u)=A_{1} \cdots A_{m-1} B_{n}^{* j} A_{m}^{i *} B_{n-1} \cdots B_{1}
$$

are $\left(A_{m-1}, B_{n}^{* j}\right)$ and $\left(A_{m}^{i *}, B_{n-1}\right)$. If $\left(A_{m-1}, B_{n}^{* j}\right)$ is an edge pair and $\mathcal{T}_{k l}^{m-1}$ is defined on $\mathcal{T}_{i j}^{m}(u)$, then

$$
\mathcal{T}_{k l}^{m-1} \mathcal{T}_{i j}^{m}(u)=A_{1} \cdots A_{m-2} B_{n}^{* j * l} A_{m-1}^{k *} A_{m}^{i *} B_{n-1} \cdots B_{1},
$$

and so on. In this manner, iterate $\mathcal{T}$ on each element $u \in X_{m}^{n+1} \times Y_{n}^{m+1}$ in all possible
ways and obtain

$$
Z_{n, m}=\left\{\mathcal{T}_{i_{t} j_{t}}^{k_{t}} \ldots \mathcal{T}_{i_{1} j_{1}}^{k_{1}}(u) \mid u \in X_{m}^{n+1} \times Y_{n}^{m+1}, t \geqslant 1\right\}
$$

Then

$$
\mathcal{P} \mathcal{P}_{n, m}=X_{m}^{n+1} \times Y_{n}^{m+1} \cup Z_{n, m}
$$

To extend the partial ordering to $Z_{n, m}$, first define $c<\mathcal{T}_{i j}^{k}(c)$ for $c \in \mathcal{P} \mathcal{P}_{n, m}$. To define a generating relation on $Z_{n, m}$, note that each composition $\mathcal{T}_{i_{t} j_{t}}^{k_{t}} \cdots \mathcal{T}_{i_{1} j_{1}}^{k_{1}}$ defined on $u \in X_{m}^{n+1} \times Y_{n}^{m+1}$ uniquely determines an $(m, n)$-shuffle $\sigma$, in which case we denote

$$
\mathcal{T}_{\sigma}(u)=\mathcal{T}_{i_{t} j_{t}}^{k_{t}} \cdots \mathcal{T}_{i_{1} j_{1}}^{k_{1}}(u)
$$

and define $\mathcal{T}_{\text {Id }}=\mathrm{Id}$. When $\mathcal{T}_{\sigma}(u)$ is defined, multiple compositions of $(i, j)$-transpositions on $u$ may determine the same $\sigma$; thus $\mathcal{T}_{\sigma}(u)$ is a set, in general. For $u_{1} \leqslant u_{2} \in X_{m}^{n+1} \times Y_{n}^{m+1}$, define $\mathcal{T}_{\sigma}\left(u_{1}\right) \leqslant \mathcal{T}_{\sigma}\left(u_{2}\right)$ if $\left(u_{1}, u_{2}\right)$ is an edge of $X_{m}^{n+1} \times Y_{n}^{m+1}$ or $u_{2}$ is " $\sigma$-compatible" with $u_{1}$ in the following sense: Let $a=$ $a_{1}|\cdots| a_{m} \in S_{m}$ and $b=b_{1}|\cdots| b_{n} \in S_{n}$. The action of $\sigma$ on $(a ; b)$ decomposes $a$ and $b$ into subsequences $\mathbf{m}_{1}, \ldots, \mathbf{m}_{k}$ and $\mathbf{n}_{1}, \ldots, \mathbf{n}_{l}$ in one of the following four ways:

$$
\sigma(a ; b)= \begin{cases}\mathbf{m}_{1}, \mathbf{n}_{1}, \mathbf{m}_{2}, \mathbf{n}_{2}, \ldots, \mathbf{n}_{k-1}, \mathbf{m}_{k}, & \sigma\left(a_{1}\right)=a_{1}, \sigma\left(b_{n}\right) \neq b_{n} \\ \mathbf{m}_{1}, \mathbf{n}_{1}, \mathbf{m}_{2}, \mathbf{n}_{2}, \ldots, \mathbf{m}_{k}, \mathbf{n}_{k}, & \sigma\left(a_{1}\right)=a_{1}, \sigma\left(b_{n}\right)=b_{n} \\ \mathbf{n}_{1}, \mathbf{m}_{1}, \mathbf{n}_{2}, \mathbf{m}_{2}, \ldots, \mathbf{n}_{k}, \mathbf{m}_{k}, & \sigma\left(a_{1}\right) \neq a_{1}, \sigma\left(b_{n}\right) \neq b_{n} \\ \mathbf{n}_{1}, \mathbf{m}_{1}, \mathbf{n}_{2}, \mathbf{m}_{2}, \ldots, \mathbf{m}_{k}, \mathbf{n}_{k+1}, & \sigma\left(a_{1}\right) \neq a_{1}, \sigma\left(b_{n}\right)=b_{n}\end{cases}
$$

Define $\quad \mathbf{I}_{\sigma}=\left\{\left(\alpha_{1}, \ldots, \alpha_{n+1}\right) \in S_{m}^{\times n+1} \mid \alpha_{i} \in S_{\# \mathbf{m}_{1}} \times \cdots \times S_{\# \mathbf{m}_{k}} \subset S_{m}\right\}$ for all $i$ and $\mathbf{J}_{\sigma}=\left\{\left(\beta_{1}, \ldots, \beta_{m+1}\right) \in S_{n}^{\times m+1} \mid \beta_{j} \in S_{\# \mathbf{n}_{1}} \times \cdots \times S_{\# \mathbf{n}_{l}} \subset S_{n}\right\}$ for all $j$. Let $\chi: \mathcal{V}_{m} \rightarrow \mathcal{V}_{m}$ be the involutory bijection defined by

$$
\chi\left(a_{1}|\cdots| a_{m}\right)=\left(m+1-a_{m}\right)|\cdots|\left(m+1-a_{1}\right)
$$

and fix the inclusion of posets

$$
\begin{equation*}
X_{m}^{n+1} \times Y_{n}^{m+1} \stackrel{\kappa}{\hookrightarrow} \mathcal{V}_{m}^{\times n+1} \times \mathcal{V}_{n}^{\times m+1} \leftrightarrow S_{m}^{\times n+1} \times S_{n}^{\times m+1} \tag{16}
\end{equation*}
$$

where $\kappa=(\chi \circ \hat{\ell})^{\times n+1} \times(\check{\ell})^{\times m+1}$. Then $u_{2}$ is $\sigma$-compatible with $u_{1}$ if $u_{2}=$ $(\alpha \times \beta)\left(u_{1}\right)$ for some $\alpha \times \beta \in \mathbf{I}_{\sigma} \times \mathbf{J}_{\sigma}$.

To view this geometrically, suppose $u_{2}=A_{1}^{\prime} \cdots A_{m}^{\prime} B_{n}^{\prime} \cdots B_{1}^{\prime}$ is $\sigma$-compatible with $u_{1}=A_{1} \cdots A_{m} B_{n} \cdots B_{1}$ in $X_{m}^{n+1} \times Y_{n}^{m+1}$. For each $i$, let $a_{i}=i_{1}|\cdots| i_{m}$ and $a_{i}^{\prime}=$ $i_{1}^{\prime}|\cdots| i_{m}^{\prime}$ be the permutations of $\underline{m}$ corresponding with the up-rooted trees given by $\gamma$-products $A_{i, 1} \cdots A_{i, m}$ and $A_{i, 1}^{\prime} \cdots A_{i, m}^{\prime}$ of $i^{\text {th }}$ rows, respectively; dually, for each $j$, let $b_{j}=j_{1}|\cdots| j_{n}$ and $b_{j}^{\prime}=j_{1}^{\prime}|\cdots| j_{n}^{\prime}$ be the permutations of $\underline{n}$ corresponding with the down-rooted trees given by the $\gamma$-products $B_{n, j} \cdots B_{1, j}$ and $B_{n, j}^{\prime} \cdots B_{1, j}^{\prime}$ of $j^{\text {th }}$ columns, respectively. Then for each $(i, j)$, the $\sigma$-partition of $\left(a_{i} ; b_{j}\right)$ determines a product face $\mathbf{m}_{1}|\cdots| \mathbf{m}_{k} \times \mathbf{n}_{1}|\cdots| \mathbf{n}_{l} \subset P_{m} \times P_{n}$ containing the vertices $a_{i} \times b_{j}$ and $a_{i}^{\prime} \times b_{j}^{\prime}$ and an oriented path of edges from $a_{i} \times b_{j}$ to $a_{i}^{\prime} \times b_{j}^{\prime}$.

## Remark 7.5.

(i) The map $\chi$ used to define the poset structure of $\mathcal{P} \mathcal{P}_{n, m}$ is evoked to induce the correct orientation of the quotient poset $\mathcal{K} \mathcal{K}_{n+1, m+1}$ (see below), and is
necessary to establish the bijection in Theorem 1 (see also item (iii) below). For geometric realizations of $\mathcal{K} \mathcal{K}_{n+1, m+1}$ and $\mathcal{K} \mathcal{K}_{m+1, n+1}$ compare Figures 21 and 22 .
(ii) Note that if $\left(u_{1}, u_{2}\right)$ is an edge of $X_{m}^{n+1} \times Y_{n}^{m+1}$, the partial ordering in $\mathcal{P} \mathcal{P}_{n, m}$ implies that $\left(\mathcal{T}\left(u_{1}\right), \mathcal{T}\left(u_{2}\right)\right)$ is an edge of $\mathcal{P} \mathcal{P}_{n, m}$.
(iii) The transpose map $X_{m}^{n+1} \times Y_{n}^{m+1} \rightarrow X_{n}^{m+1} \times Y_{m}^{n+1}$ given by

$$
A_{1} \cdots A_{m} B_{n} \cdots B_{1} \mapsto B_{1}^{T} \cdots B_{n}^{T} A_{m}^{T} \cdots A_{1}^{T}
$$

induces a canonical order-preserving bijection $\mathcal{P} \mathcal{P}_{n, m} \leftrightarrow \mathcal{P} \mathcal{P}_{m, n}$.

Example 7.6. Using the notation of Example 7.1, let us determine those elements $u_{i} \in X_{2}^{2} \times Y_{1}^{3}$ that are $\sigma$-compatible with $u_{1}$. Since all matrices in $u_{1}$ have constant columns or rows, $a_{i} \times b_{j}=1 \mid 2 \times 1 \subset P_{2} \times P_{1}$ for all $i, j$. The $(2,1)$-shuffles of $(1,2 ; 3)$ are $\sigma_{0}=1|2| 3, \sigma_{1}=1|3| 2$ and $\sigma_{2}=3|1| 2$. The $\sigma_{1}$-partition of $(1 \mid 2 ; 1)$ determines the face $1 \mid 2 \times 1 \subset P_{2} \times P_{1}$ whose only vertex is $u_{1}$. Hence the only element of $X_{2}^{2} \times Y_{1}^{3}$ that is $\sigma_{1}$-compatible with $u_{1}$ is itself. If $\sigma \in\left\{\sigma_{0}, \sigma_{2}\right\}$, the $\sigma$-partition of $(1 \mid 2 ; 1)$ determines the face $12 \times 1 \subset P_{2} \times P_{1}$ with vertices are $1 \mid 2 \times 1$ and $2 \mid 1 \times 1$. Since all matrices in $u_{3}$ have constant columns or rows, $a_{i}^{\prime} \times b_{j}^{\prime}=2 \mid 1 \times 1$ for all $i, j$ implies that $u_{3}$ is $\sigma$-compatible with $u_{1}$. Furthermore, $a_{1}^{\prime} \times b_{j}^{\prime}=1 \mid 2 \times 1$ and $a_{2}^{\prime} \times b_{j}^{\prime}=2 \mid 1 \times 1$ for all $j$ implies that $u_{2}$ is also $\sigma$-compatible with $u_{1}$. Since $u_{1}<u_{3}$ we have $\mathcal{T}_{\sigma_{2}}\left(u_{1}\right)<$ $\mathcal{T}_{\sigma_{2}}\left(u_{3}\right)$.

Example 7.7. Since $Z_{1,1}=[\curlyvee][\lambda]$ we have

$$
\mathcal{P P}_{1,1}=\left\{\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right][\curlyvee \curlyvee]<[\curlyvee][\curlywedge]\right\} .
$$

Using the notation of Example 7.6, the action of $\mathcal{T}$ on

$$
u_{1}=\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1} \\
\curlywedge & \mathbf{1}
\end{array}\right]\left[\begin{array}{llr}
\curlyvee & \curlyvee & \curlyvee
\end{array}\right] \text { and } u_{3}=\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\mathbf{1} & \curlywedge \\
\mathbf{1} & \curlywedge
\end{array}\right]\left[\begin{array}{lll}
\curlyvee & \curlyvee & \curlyvee
\end{array}\right]
$$

produces the following four elements of $Z_{1,2}$ :

$$
\begin{aligned}
& u_{1} \stackrel{\mathcal{T}_{\sigma_{1}}}{\longmapsto}\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{l}
\curlyvee
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1}
\end{array}\right] \stackrel{\mathcal{T}_{\sigma_{2}}}{\longmapsto}[\curlyvee][\curlywedge]\left[\begin{array}{ll}
\curlywedge & \mathbf{1}
\end{array}\right] ; \\
& u_{3} \stackrel{\mathcal{T}_{\sigma_{1}}}{\longmapsto}\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right][\curlyvee \curlyvee]\left[\begin{array}{ll}
\mathbf{1} & \curlywedge
\end{array}\right] \stackrel{\mathcal{T}_{\sigma_{2}}}{\longmapsto}[\curlyvee][\curlywedge]\left[\begin{array}{ll}
\mathbf{1} & \curlywedge
\end{array}\right] .
\end{aligned}
$$

Thus $\mathcal{P} \mathcal{P}_{1,2}=\left\{u_{1}<\mathcal{T}_{\sigma_{1}}\left(u_{1}\right)<\mathcal{T}_{\sigma_{2}}\left(u_{1}\right), u_{2}, u_{3}<\mathcal{T}_{\sigma_{1}}\left(u_{3}\right)<\mathcal{T}_{\sigma_{2}}\left(u_{3}\right)\right\}$. Recall that the action of $\mathcal{T}$ on $u_{2}$ is undefined, and as mentioned in Examples 7.1 and 7.6, $u_{1}<u_{2}<u_{3}$ and $\mathcal{T}_{\sigma_{2}}\left(u_{1}\right)<\mathcal{T}_{\sigma_{2}}\left(u_{3}\right)$ (see Figure 12).

Figure 12: The digraph of $\mathcal{P} \mathcal{P}_{1,2}$.
One can represent $u=A_{1} \cdots A_{m} B_{n} \cdots B_{1} \in X_{m}^{n+1} \times Y_{n}^{m+1}$ and $z=\mathcal{T}_{\sigma}(u) \in Z_{n, m}$ as piecewise linear paths of from $(m+1,1)$ to $(1, n+1)$ in the integer lattice $\mathbb{N}^{2}$ with $m+n$ horizontal and vertical directed components. The arrow $(i+1, n+1) \rightarrow$ $(i, n+1)$ represents $A_{i}$, while the arrow $(m+1, j) \rightarrow(m+1, j+1)$ represents $B_{j}$. Consequently, $u$ is represented by the path

$$
(m+1,1) \rightarrow \cdots \rightarrow(m+1, n+1) \rightarrow \cdots \rightarrow(1, n+1)
$$

and $z$ is represented by some other path. In general, if the path $(r+1, s-1) \rightarrow$ $(r+1, s) \rightarrow(r, s)$ represents the edge pair $\left(A_{k}^{\prime}, B_{l}^{\prime}\right)$ in $z$, the path $(r+1, s-1) \rightarrow$ $(r, s-1) \rightarrow(r, s)$ represents its transposition $\left(B_{l}^{\prime \prime}, A_{k}^{\prime \prime}\right)$ in $\mathcal{T}(z)$ (see Figure 13).

Figure 13: $A_{1} A_{2} A_{3} B_{2} B_{1}<A_{1} A_{2} B_{2}^{\prime} A_{3}^{\prime} B_{1}<A_{1} B_{2}^{\prime \prime} A_{2}^{\prime} A_{3}^{\prime} B_{1}$.

The poset $\mathcal{K} \mathcal{K}$ is a quotient of $\mathcal{P} \mathcal{P}$, which we now describe. Recall Tonks' projection $\vartheta_{0}: P_{m} \rightarrow K_{m+1}$ [15]: If $a$ and $b$ are faces of $P_{m}$, then $\vartheta_{0}(a)=\vartheta_{0}(b)$ if and only if corresponding PLTs are isomorphic as planar rooted trees (forgetting levels). Define
$a \sim b$ if $\vartheta_{0}(a)=\vartheta_{0}(b)$. Then $\tilde{\mathcal{V}}_{m+1}=\vartheta_{0}\left(\mathcal{V}_{m}\right)$ is the set of vertices of $K_{m+1}$. For example, $3|1| 2=1|3| 2 \in \tilde{\mathcal{V}}_{4}$, since $3|1| 2$ and $1|3| 2$ are end points of the degenerate edge $13 \mid 2 \subset P_{3}$, and in terms matrix sequences we have $[\curlywedge]\left[\begin{array}{lll}\curlywedge & \mathbf{1}\end{array}\right]\left[\begin{array}{lll}1 & 1 & \curlywedge\end{array}\right]=[\curlywedge]\left[\begin{array}{lll}\mathbf{1} & \curlywedge\end{array}\right]\left[\begin{array}{lll}\curlywedge & 1 & 1\end{array}\right]$ (and dually $\left.\left[\begin{array}{lll}\mathbf{1} & 1 & \curlyvee\end{array}\right]^{T}[\curlyvee \mathbf{1}]^{T}[\curlyvee]=\left[\begin{array}{lll}\curlyvee & \mathbf{1}\end{array}\right]^{T}\left[\begin{array}{ll}\mathbf{1} & \curlyvee\end{array}\right]^{T}[\curlyvee]\right)$. Of course, $\mathcal{V}_{1}=\tilde{\mathcal{V}}_{2}=[\curlywedge]$ and $\mathcal{V}_{2}=\tilde{\mathcal{V}}_{3}=\left\{[\curlywedge][\curlywedge \mathbf{1}],[\curlywedge]\left[\begin{array}{ll}\mathbf{1} & \wedge\end{array}\right]\right\}$.

For matrix sequences in $X_{m}^{n+1}$, define $x_{1}^{\prime} \cdots x_{m}^{\prime} \sim_{X} x_{1} \cdots x_{m}$ if the trees produced by $\gamma$-products of $i^{t h}$ rows are equivalent for each $i$. Dually, for matrix sequences in $Y_{n}^{m+1}$, define $y_{n}^{\prime} \cdots y_{1}^{\prime} \sim_{Y} y_{n} \cdots y_{1}$ if the trees produced by $\gamma$-products of $j^{t h}$ columns are equivalent for each $j$. Define $a \times b \sim c \times d$ in $X_{m}^{n+1} \times Y_{n}^{m+1}$ if $a \sim_{X} c$ and $b \sim_{Y} d$. Finally, for $u_{1} \leqslant u_{2} \in X_{m}^{n+1} \times Y_{n}^{m+1}$ and $z_{1}=\mathcal{T}_{\sigma}\left(u_{1}\right) \leqslant z_{2}=\mathcal{T}_{\sigma}\left(u_{2}\right)$, define $z_{1} \sim z_{2}$ if $u_{1} \sim u_{2}$. Then

$$
\mathcal{K} \mathcal{K}_{n+1, m+1}=\mathcal{P} \mathcal{P}_{n, m} / \sim
$$

and $\vartheta \vartheta: \mathcal{P} \mathcal{P}_{n, m} \rightarrow \mathcal{K} \mathcal{K}_{n+1, m+1}$ denotes the projection.

## 8. The Combinatorial Join of Permutahedra

The combinatorial join of permutahedra, which resembles the standard join of spaces, plays an important role in our construction of the biassociahedra to follow. The combinatorial join $P_{m} *_{c} P_{n}$ of permutahedra $P_{m}$ and $P_{n}$ is the permutahedron $P_{m+n}$ constructed as follows: Given faces $A_{1}|\cdots| A_{k} \subseteq P_{m}$ and $B_{1}|\cdots| B_{l} \subseteq P_{n}$, let $s$ be an integer such that max $\{k, l\} \leqslant s \leqslant k+l$, and let $(\mathbf{i} ; \mathbf{j})=\left(i_{1}<\cdots<\overline{i_{k}} ; j_{1}<\cdots<j_{l}\right)$, where $\mathbf{i} \cup \mathbf{j}=\underline{s}$. Obtain $A_{1}^{\prime}|\cdots| A_{s}^{\prime}$ and $B_{1}^{\prime}|\cdots| B_{s}^{\prime}$ by setting $A_{i_{r}}^{\prime}=A_{r}, B_{j_{t}}^{\prime}=B_{t}$, and $A_{i}^{\prime}=B_{j}^{\prime}=\varnothing$ otherwise. Note that $\left(A_{r}^{\prime}, B_{r}^{\prime}\right) \neq(\varnothing, \varnothing)$ for all $r$. Given a set $B=$ $\left\{b_{1}, \ldots, b_{k}\right\} \subset \mathbb{N}$ and $m \in \mathbb{N}$, define $B+m=\left\{b_{1}+m, \ldots, b_{k}+m\right\}$ and consider the codimension $s-1$ face

$$
A_{1}|\cdots| A_{k} *(\mathbf{i} \mathbf{j} \mathbf{j}) B_{1}|\cdots| B_{l}=A_{1}^{\prime} \cup\left(B_{1}^{\prime}+m\right)|\cdots| A_{s}^{\prime} \cup\left(B_{s}^{\prime}+m\right) \subset P_{m+n}
$$

When $s=m+n$, each pair of vertices $A_{1}|\cdots| A_{m} \times B_{1}|\cdots| B_{n} \subset P_{m} \times P_{n}$ generates $\binom{m+n}{m}$ vertices $A_{1}|\cdots| A_{m} *_{(\mathbf{i} \mathbf{j})} B_{1}|\cdots| B_{n}$ of $P_{m+n}$ as $(\mathbf{i} ; \mathbf{j})$ ranges over all $(m, n)$ shuffles of $\left(A_{1}, \ldots, A_{m} ; B_{1}+m, \ldots, B_{n}+m\right)$. Define

$$
P_{m} *_{c} P_{n}=\bigcup_{\substack{A_{1}|\cdots| A_{k} \times B_{1}|\cdots| B_{l} \subseteq P_{m} \times P_{m} \\ \mathbf{i} \cup \mathbf{j}=\underline{s} ; \max \{k, l\} \leqslant s \leqslant k+l}} A_{1}|\cdots| A_{k} *(\mathbf{i} ; \mathbf{j}) B_{1}|\cdots| B_{l}
$$

Thus, given $m, n \geqslant 1$ and a cell $e \subseteq P_{m+n}$, there is a unique decomposition $e=$ $A_{1}|\cdots| A_{k} *_{(\mathbf{i} \mathbf{j})} B_{1}|\cdots| B_{l}$ with $A_{1}|\cdots| A_{k} \subset P_{m}$ and $B_{1}|\cdots| B_{l} \subset P_{n}$.
Example 8.1. Setting $s=2$ produces the 14 codimension 1 faces of $P_{2} *_{c} P_{2}=P_{4}$ :

| $(\mathbf{i} ; \mathbf{j})$ | $A$ | $B$ | $A *_{(\mathbf{i} ; \mathbf{j})} B$ |
| :---: | :---: | :---: | :---: |
| $(1,2 ; 1,2)$ | $1 \mid 2$ | $1 \mid 2$ | $13 \mid 24$ |
|  | $1 \mid 2$ | $2 \mid 1$ | $14 \mid 23$ |
|  | $2 \mid 1$ | $1 \mid 2$ | $23 \mid 14$ |
|  | $2 \mid 1$ | $2 \mid 1$ | $24 \mid 13$ |
| $(1 ; 1,2)$ | 12 | $1 \mid 2$ | $123 \mid 4$ |
|  | 12 | $2 \mid 1$ | $124 \mid 3$ |
| $(1 ; 2)$ | 12 | 12 | $12 \mid 34$ |

| $(\mathbf{i} ; \mathbf{j})$ | $A$ | $B$ | $A *_{(\mathbf{i} \mathbf{j})} B$ |
| :---: | :---: | :---: | :---: |
| $(2 ; 1,2)$ | 12 | $1 \mid 2$ | $3 \mid 124$ |
|  | 12 | $2 \mid 1$ | $4 \mid 123$ |
| $(1,2 ; 1)$ | $1 \mid 2$ | 12 | $134 \mid 2$ |
|  | $2 \mid 1$ | 12 | $234 \mid 1$ |
| $(1,2 ; 2)$ | $1 \mid 2$ | 12 | $1 \mid 234$ |
|  | $2 \mid 1$ | 12 | $2 \mid 134$ |
| $(2 ; 1)$ | 12 | 12 | $34 \mid 12$ |

Fraction products $a / b$ reappear as combinatorial joins $a *_{c} b$ in Step 2 of the construction that follows in the next section.

## 9. Constructions of $P P$ and $K K$

We conclude the paper with constructions of the geometric realizations $P P=|\mathcal{P} \mathcal{P}|$ and $K K=|\mathcal{K} \mathcal{K}|$. While the edges of $P P$ and $K K$ realize the edges of $\mathcal{P P}$ and $\mathcal{K} \mathcal{K}$, it is difficult to imagine their higher dimensional faces. Fortunately, $P P_{n, m}$ is a subdivision of the permutahedron $P_{m+n}$, which is a subdivision of $I^{n+m-1}$. Thus the higher dimensional combinatorics of $P P_{n, m}$ are determined by the orientation on the faces of $I^{m+n-1}$.

Our construction of $P P_{n, m}$ has two steps: (1) Perform an " $(m, n)$-subdivision" of the codimension 1 cell $\underline{m} \mid(\underline{n}+m) \subset P_{m+n}$ and (2) use the $(m, n)$-subdivision to subdivide certain other cells of $P_{m+n}$. We emphasize that $\Delta_{P}$ is used only in step (1) and only in terms of its geometrical definition. Thus the non-coassociativity and non-cocommutativity of $\Delta_{P}$ are not in play here (see also Remark 9.4 below). We begin with some preliminaries.

### 9.1. Matrices with constant rows or columns

Given a set $Q$ of matrix sequences, let

$$
\operatorname{con} Q=\left\{C_{1} \cdots C_{s} \in Q \mid C_{k} \text { has constant rows or constant columns }\right\}
$$

Note that if $A_{1} \cdots A_{m} \in \operatorname{con} X_{m}^{n+1}$, each $A_{i}$ has constant columns; dually, if $B_{n} \cdots B_{1}$ $\in \operatorname{con} Y_{n}^{m+1}$, each $B_{j}$ has constant rows. Consequently, the inclusion of posets $\kappa: X_{m}^{n+1} \times Y_{n}^{m+1} \hookrightarrow \mathcal{V}_{m}^{\times n+1} \times \mathcal{V}_{n}^{\times m+1}$ given in (16) restricts to an order-preserving bijection

$$
\begin{align*}
(\chi \circ \hat{\ell}) \times \check{\ell}: \operatorname{con}\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right) & \leftrightarrow \operatorname{con} X_{m}^{n+1} \times \operatorname{con} Y_{n}^{m+1} \\
& \leftrightarrow \Delta\left(\mathcal{V}_{m}^{\times n+1}\right) \times \Delta\left(\mathcal{V}_{n}^{\times m+1}\right) \leftrightarrow \mathcal{V}_{m} \times \mathcal{V}_{n} \tag{17}
\end{align*}
$$

where $\Delta\left(\mathcal{V}_{m}^{\times n+1}\right) \leftrightarrow \mathcal{V}_{m}$ is given by the embedding $\mathcal{V}_{m} \hookrightarrow \mathcal{V}_{m}^{\times n+1}$ along the diagonal subposet $\Delta\left(\mathcal{V}_{m}^{\times n+1}\right)=\left\{(v, \ldots, v) \mid v \in \mathcal{V}_{m}\right\}$. Thus elements of $\mathcal{V}_{m} \times \mathcal{V}_{n}$ may be represented as matrix strings in con $\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right)$.

Note that $(i, j)$-transpositions preserve constant rows and columns, i.e., $u \in \operatorname{con} \mathcal{P} \mathcal{P}_{n, m}$ if and only if $\mathcal{T}_{i j}^{k}(u) \in \operatorname{con} \mathcal{P} \mathcal{P}_{n . m}$. And furthermore, if $u=A_{1} \cdots A_{m}$ $B_{n} \cdots B_{1} \in \operatorname{con}\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right)$ and $\sigma$ is an $(m, n)$-shuffle, $\mathcal{T}_{\sigma}(u)$ is defined since each $A_{i}$ has a constant column of $\lambda$ 's and each $B_{j}$ has a constant row of $\gamma$ 's. Thus

$$
\begin{equation*}
\operatorname{con} \mathcal{P} \mathcal{P}_{n, m}=\bigcup_{(m, n) \text {-shuffles } \sigma} \mathcal{T}_{\sigma}\left(\operatorname{con}\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right)\right) \tag{18}
\end{equation*}
$$

The order-preserving bijection

$$
\operatorname{con} \mathcal{P P}_{1,2}=\mathcal{P} \mathcal{P}_{1,2} \backslash\left\{u_{2}\right\} \leftrightarrow \mathcal{V}_{3}
$$

discussed in Example 7.7 illustrates the following remarkable fact:

Proposition 9.1. The bijection

$$
(\chi \circ \hat{\ell}) \times \check{\ell}: \operatorname{con}\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right) \rightarrow \mathcal{V}_{m} \times \mathcal{V}_{n}
$$

extends to a canonical order-preserving bijection

$$
\kappa_{\#}: \operatorname{con} \mathcal{P} \mathcal{P}_{n, m} \rightarrow \mathcal{V}_{m+n}
$$

Thus $\left|\kappa_{\#}\right|:\left|\operatorname{con} \mathcal{P} \mathcal{P}_{n, m}\right| \xrightarrow{\approx} P_{m+n}$.
Proof. There is the order-preserving bijection $(\chi \circ \hat{\ell}) \times \check{\ell}: \operatorname{con}\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right) \leftrightarrow$ $S_{m} \times S_{n}$ via the identification $\mathcal{V}_{m} \times \mathcal{V}_{n} \leftrightarrow S_{m} \times S_{n}$. Thus

$$
\operatorname{con} \mathcal{P} \mathcal{P}_{n, m} \leftrightarrow\left\{\sigma \circ\left(\sigma_{m} \times \sigma_{n}\right) \mid \sigma \text { is an }(m, n) \text {-shuffle; } \sigma_{m} \times \sigma_{n} \in S_{m} \times S_{n}\right\}
$$

by formula (18). But each permutation in $S_{m+n}$ factors as $\sigma \circ\left(\sigma_{m} \times \sigma_{n}\right)$ for some $(m, n)$-shuffle $\sigma$ and some $\sigma_{m} \times \sigma_{n} \in S_{m} \times S_{n}$. Therefore $(\chi \circ \hat{\ell}) \times \check{\ell}$ extends to $\kappa_{\#}: \operatorname{con} \mathcal{P P}_{n, m} \leftrightarrow S_{m+n} \leftrightarrow \mathcal{V}_{m+n}$.

Corollary 9.2. For all $m, n \geqslant 1$, there is the commutative diagram

$$
\begin{array}{ccc}
\left|\operatorname{con}\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right)\right| & \hookrightarrow & \left|\operatorname{con} \mathcal{P} \mathcal{P}_{n, m}\right| \\
|\kappa| \downarrow \approx & & \approx \downarrow\left|\kappa_{\#}\right| \\
\underline{m} \mid(\underline{n}+m) & \hookrightarrow & P_{m+n}
\end{array}
$$

Note that if $\chi_{\#}: \mathcal{V}_{m+n} \rightarrow \mathcal{V}_{m+n}$ were induced by the composition $\mathcal{V}_{m} \times \mathcal{V}_{n} \xrightarrow{\chi \times 1}$ $\mathcal{V}_{m} \times \mathcal{V}_{n} \hookrightarrow \mathcal{V}_{m+n}$ in the same manner as $\kappa_{\#}$, then $\chi_{\#}$ and $\chi$ would differ on $\mathcal{V}_{m+n}$ even with $n=1$.

Example 9.3. Continuing Example 7.7, the identification $\operatorname{con} \mathcal{P} \mathcal{P}_{1,1} \leftrightarrow \mathcal{V}_{2}$ is given by

$$
\begin{array}{ccc}
{\left[\begin{array}{c}
\curlywedge \\
\curlywedge
\end{array}\right][\curlyvee \curlyvee]} & \xrightarrow{\mathcal{T}} & {[\curlyvee][\curlywedge]} \\
\imath & & \downarrow \\
1 \mid(1+1) & \underset{(1,1) \text {-shuffle }}{\longrightarrow} & 2 \mid 1 .
\end{array}
$$

The identification con $\mathcal{P} \mathcal{P}_{1,2} \leftrightarrow \mathcal{V}_{3}$ :

$$
\left.\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1} \\
\curlywedge & \mathbf{1}
\end{array}\right] \leftrightarrow 1 \right\rvert\, 2 \in S_{2} \text { and }[\curlyvee \gamma \gamma] \leftrightarrow 1 \in S_{1}
$$

so that

$$
u_{1}=\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1} \\
\curlywedge & \mathbf{1}
\end{array}\right]\left[\begin{array}{lll}
\curlyvee & \curlyvee & \curlyvee
\end{array}\right] \leftrightarrow 1|2|(1+2)=1|2| 3 \in S_{2} \times S_{1} .
$$

Similarly,

$$
u_{3}=\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\mathbf{1} & \curlywedge \\
1 & \curlywedge
\end{array}\right][\curlyvee \gamma \gamma] \leftrightarrow 2|1|(1+2)=2|1| 3 \in S_{2} \times S_{1}
$$

and we have

$(2,1)$-shuffles of $2|1| 3$.
The projection $\vartheta$ : con $\mathcal{P} \mathcal{P}_{n, m} \rightarrow \operatorname{con} \mathcal{P} \mathcal{P}_{n, m} / \sim$ has the following simple geometrical interpretation: An element of $\operatorname{con}\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right)$ is represented by a fraction with multiple copies of the same leveled binary tree in the numerator and likewise in the denominator. Two such elements are equivalent if and only if the trees in their numerators or denominators (possibly both) are isomorphic as PRTs. So equivalence in con $\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right)$ amounts to forgetting levels as in Tonks' projection. The poset structure then propagates this equivalence to general elements of $\operatorname{con} \mathcal{P} \mathcal{P}_{n, m}$.

Remark 9.4. Our constructions are independent of the various choices involved here. If $\tilde{\Delta}_{P}^{(k)}$ iterates $\Delta_{P}$ on factors other than the those on the extreme left, let $\widetilde{X}_{m}^{n+1} \times \widetilde{Y}_{n}^{m+1}$ be the poset defined in terms of $\tilde{\Delta}_{P}^{(k)}$ and let $\widetilde{\mathcal{P P}}_{n, m}$ be the poset produced by our construction. Then there is a canonical bijection $\mathcal{P} \mathcal{P}_{n, m} \leftrightarrow \widetilde{\mathcal{P P}}_{n, m}$ and the corresponding geometric realizations are canonically homeomorphic. When $\Delta_{P}$ acts on the extreme right, for example, a (combinatorial) isomorphism $\left|\mathcal{P} \mathcal{P}_{n, m}\right| \cong$ $\left|\widetilde{\mathcal{P P}}_{n, m}\right|$ is evident pictorially: The picture of $\left|\mathcal{P} \mathcal{P}_{n, m}\right|$ uses the standard orientation of the interval $P_{2}$, while the picture of $\left|\widetilde{\mathcal{P P}}_{n, m}\right|$ uses the opposite orientation, but nevertheless, these pictures are identical.

### 9.2. Step 1: The $(m, n)$-subdivision of $\underline{m} \mid(\underline{n}+m)$

The first step in our construction of $P P_{n, m}$ performs an " $(m, n)$-subdivision" of the codimension 1 cell $\underline{m} \mid(\underline{n}+m) \subset P_{n+m}$. In Subsection 5.2 we applied the leftiterated diagonal $\Delta_{P}^{(n)}$ to construct the $n$-subdivision $P_{m}^{(n)}$ of $P_{m}$. Since the poset $X_{m}^{n+1}$ is the 0 -skeleton of $\Delta^{(n)}\left(P_{m}\right)$, the geometric realization $\left|X_{m}^{n+1}\right|=P_{m}^{(n)}$, and dually $\left|Y_{n}^{m+1}\right|=P_{n}^{(m)}$. The cellular subdivision $\left|X_{m}^{n+1} \times Y_{n}^{m+1}\right|=P_{m}^{(n)} \times P_{n}^{(m)}$ of $\underline{m} \mid(\underline{n}+m)=P_{m} \times P_{n}$ is called the $(m, n)$-subdivision of $\underline{m} \mid(\underline{n}+m)$; thus each cell

Figure 14: The $(2,2)$-subdivision $P_{2}^{(2)} \times P_{2}^{(2)}$.
in this subdivision has a canonical Cartesian product decomposition. The basic subdivision vertices of $P P_{n, m}$ are elements of

$$
\mathcal{B} \mathcal{S}_{n, m}=\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right) \backslash \mathcal{V}_{m+n}
$$

Each subdivision cell of $P P_{n, m}$ is a proper subset of some cell of $P_{m+n}$ and is the geometric realization of its poset of vertices.
Example 9.5. The 1-subdivision $P_{2}^{(1)}$ consists of two 1-cells obtained by subdividing the interval $P_{2}$ at its midpoint (see Figure 7). Thus the (2,1)-subdivision $P_{2}^{(1)} \times P_{1}^{(2)}$ of the edge $12 \mid 3 \subset P_{3}$ contains one basic subdivision vertex represented by the midpoint

$$
u_{2}=\left[\begin{array}{l}
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1} \\
\mathbf{1} & \curlywedge
\end{array}\right]\left[\begin{array}{lrr}
\curlyvee & \curlyvee
\end{array}\right] \in X_{2}^{2} \times Y_{1}^{3} \backslash \operatorname{con}\left(X_{2}^{2} \times Y_{1}^{3}\right),
$$

and two 1-cells of $P P_{1,2}$. In fact, $P P_{1,2}$ is exactly the heptagon obtained by subdividing $P_{3}$ in this way. The 2-subdivision $P_{2}^{(2)}$ consists of three 1-cells obtained by subdividing $P_{2}$ at its midpoint and again at its three-quarter point. Thus the (2,2)subdivision $P_{2}^{(2)} \times P_{2}^{(2)}$ of the square $12 \mid 34 \subset P_{4}$ contains twelve basic subdivision vertices and nine 2-cells of $P P_{2,2}$ as pictured in Figure 14.

The $(3,1)$-subdivision $P_{3}^{(1)} \times P_{1}^{(3)}$ of the hexagon $123 \mid 4 \subset P_{4}$ is identified with the 1-subdivision $P_{3}^{(1)}$ and contains eleven basic subdivision vertices and eight 2-cells of $P P_{3,1}$ as pictured in Figure 15.

The $(3,2)$-subdivision $P_{3}^{(2)} \times P_{2}^{(3)}$ of the cylinder $123 \mid 45 \subset P_{5}$, obtained from $P_{3}^{(2)} \times I$ by subdividing along the horizontal cross-sections $P_{3}^{(2)} \times \frac{1}{2}, P_{3}^{(2)} \times \frac{3}{4}$, and $P_{3}^{(2)} \times \frac{7}{8}$, contains 140 basic subdivision vertices and eighty-four 3-cells of $P P_{3,2}$. $\left(P_{3}^{(2)}\right.$ is pictured in Figure 11.)

### 9.3. Step 2: Subdividing cells of $P_{m+n} \backslash \underline{m} \mid(\underline{n}+m)$

Recall that elements of $Z_{n, m}$ arise from the non-trivial action of $\mathcal{T}_{\sigma}$ on $X_{m}^{n+1} \times Y_{n}^{m+1}$. When $\sigma$ ranges over all $(m, n)$-shuffles (including the identity), we obtain the poset

$$
\mathcal{S}_{n, m}=\bigcup_{(m, n) \text {-shuffles } \sigma} \mathcal{T}_{\sigma}\left(\mathcal{B} \mathcal{S}_{n, m}\right)
$$

of subdivision vertices of $\mathcal{P} \mathcal{P}_{n, m}$. Thus as sets, $\mathcal{P} \mathcal{P}_{n, m}=\operatorname{con} \mathcal{P} \mathcal{P}_{n, m} \sqcup \mathcal{S}_{n, m}$.

Figure 15: The (3, 1)-subdivision $P_{3}^{(1)} \times P_{1}^{(3)}$.

The second step of our construction detects those cells of $P_{m+n} \backslash \underline{m} \mid(\underline{n}+m)$ that contain subdivision vertices. We refer to such cells as Type I cells; all other cells have Type II. We use the poset structure of subdivision vertices to subdivide Type I cells, and having done so, our construction of $P P_{n, m}$ will be complete.

To begin, let us characterize those Type I cells of minimal dimension that contain non-basic subdivision vertices. If $e$ is a cell of some polytope, denote the set of vertices of $e$ by $\mathcal{V}_{e}$. Given an ( $m, n$ )-shuffle $\sigma$ and a cell $e \subset \underline{m} \mid(\underline{n}+m)$, let $\mathcal{T}(\sigma, e)$ denote the cell of $P_{m+n}$ of minimal dimension such that $\mathcal{T}_{\sigma}\left(\mathcal{V}_{e}\right) \subseteq \mathcal{V}_{\mathcal{T}(\sigma, e)}$. This defines a map

$$
\mathcal{T}:\{(m, n) \text {-shuffles }\} \times\{\text { partitions of } \underline{m} \mid(\underline{n}+m)\} \rightarrow\{\text { partitions of } \underline{m+n}\},
$$

which extends the map $\left(\sigma, \sigma_{m} \times \sigma_{n}\right) \mapsto \sigma \circ\left(\sigma_{m} \times \sigma_{n}\right)$ in the proof of Proposition 9.1. To define $\mathcal{T}$ at a particular shuffle $\sigma$ and partition

$$
e=A_{1}|\cdots| A_{k}\left|B_{1}\right| \cdots\left|B_{l} \subseteq \underline{m}\right|(\underline{n}+m),
$$

remove all block delimiters of $e$ and think of $e$ as a permutation of $\underline{m+n}$ in which $A_{i}$ and $B_{j}$ are contiguous subsequences. Consider the set $\left\{D_{1}, \ldots, D_{r}\right\}$ of all contiguous subsequences $\sigma\left(A_{i}\right)$ and $\sigma\left(B_{j}\right)$ of $\sigma(e)$ that preserve the contiguity of the $B_{j^{\prime}}$ 's and $A_{i}$ 's, respectively, then reinsert block delimiters so that

$$
\mathcal{T}(\sigma, e)=C_{1}\left|D_{i_{1}}\right| \cdots\left|C_{r}\right| D_{i_{r}} \mid C_{r+1} .
$$

Since each cell of $P_{m+n}$ can be expressed uniquely as a component of the combinatorial join $P_{m} *_{c} P_{n}$, we have

$$
\begin{equation*}
\mathcal{T}(\sigma, e)=E *_{(\mathrm{i} ; \mathrm{j})} F=E_{1}^{\prime} \cup\left(F_{1}^{\prime}+m\right)|\cdots| E_{s}^{\prime} \cup\left(F_{s}^{\prime}+m\right), \tag{19}
\end{equation*}
$$

where $E_{i}$ and $F_{j}$ are the unions of consecutive blocks $A_{i^{\prime}}|\cdots| A_{i^{\prime}+i^{\prime \prime}}$ and $B_{j^{\prime}} \mid \cdots$ $\mid B_{j^{\prime}+j^{\prime \prime}}$ of $e$, respectively. Thus $\sigma$ acts on the blocks of $e$ as a $(k, l)$-shuffle if and only if $C_{i}=\varnothing$ for all $i$ if and only if $\mathcal{T}(\sigma, e)=A_{1}|\cdots| A_{k} *_{(\mathrm{i}, \mathrm{j})} B_{1}|\cdots| B_{l}$ for some $(k, l)$-unshuffle $(\mathbf{i} \mathbf{i})=\left(i_{1}<\cdots<i_{k} ; j_{1}<\cdots<j_{l}\right)$ of $k+l$. Clearly, a cell $a \subset P_{n+m}$ contains a non-basic subdivision vertex $\mathcal{T}_{\sigma}(u)$ if and only if $a=\mathcal{T}(\sigma, e)$ for some cell $e \subset \underline{m} \mid(\underline{n}+m)$ containing a basic subdivision vertex $u$ on which $\mathcal{T}_{\sigma}$ acts non-trivially. In fact, $a$ contains at most one non-basic subdivision vertex when $m+n \leqslant 4$.

The following proposition incorporates the property of $\mathcal{T}$ described in Remark 7.5 and will be applied in our subsequent examination of the poset structure of $\mathcal{P} \mathcal{P}_{n, m}$.

Proposition 9.6. If a cell $e \subset \underline{m} \mid(\underline{n}+m)$ contains a subdivision cell $a \subset \mid X_{m}^{n+1} \times$ $Y_{n}^{m+1} \mid$ and $\mathcal{T}_{\sigma}\left(\mathcal{V}_{a}\right) \subset\left(\mathcal{S}_{n, m} \cap \mathcal{T}(\sigma, e)\right) \cup \mathcal{V}_{\mathcal{T}(\sigma, e)}$, then $\left|\mathcal{T}_{\sigma}\left(\mathcal{V}_{a}\right)\right|$ is a subdivision cell of $\mathcal{T}(\sigma, e)$ (combinatorially) isomorphic to $a$; in particular, if $a=a_{1} \times a_{2}$, then

$$
\left|\mathcal{T}_{\sigma}\left(\mathcal{V}_{a_{1} \times a_{2}}\right)\right|=\left|\mathcal{T}_{\sigma}\left(\mathcal{V}_{a_{1}}\right)\right| \times\left|\mathcal{T}_{\sigma}\left(\mathcal{V}_{a_{2}}\right)\right|
$$

Proof. Since $\mathcal{T}_{\sigma}(u)$ is defined for all $u \in \mathcal{V}_{a}$ and $\mathcal{T}_{\sigma}$ preserves the poset structure of $\mathcal{V}_{a}$, the cells $a=\left|\mathcal{V}_{a}\right|$ and $\left|\mathcal{T}_{\sigma}\left(\mathcal{V}_{a}\right)\right|$ are combinatorially isomorphic.

Example 9.7. The action of $\mathcal{T}$ on the four vertices of $12 \mid 34$ partitions the 24 vertices of $P_{4}$ into four mutually disjoint sets of six vertices each. The vertices $v_{1}=1|2| 3 \mid 4$ and $v_{2}=1|2| 4 \mid 3$ of edge $e=1|2| 34$ correspond respectively to

$$
\left[\begin{array}{l}
\curlywedge \\
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1} \\
\curlywedge & \mathbf{1} \\
\curlywedge & \mathbf{1}
\end{array}\right]\left[\begin{array}{lll}
\curlyvee & \curlyvee & \curlyvee \\
\mathbf{1} & \mathbf{1} & \mathbf{1}
\end{array}\right]\left[\begin{array}{lll}
\curlyvee & \curlyvee & \curlyvee
\end{array}\right] \text { and }\left[\begin{array}{l}
\curlywedge \\
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1} \\
\curlywedge & \mathbf{1} \\
\curlywedge & \mathbf{1}
\end{array}\right]\left[\begin{array}{lll}
\mathbf{1} & \mathbf{1} & \mathbf{1} \\
\gamma & \curlyvee & \curlyvee
\end{array}\right]\left[\begin{array}{lll}
\curlyvee & \curlyvee & \curlyvee
\end{array}\right] .
$$

There are two basic subdivision vertices $u_{1}$ and $u_{2}$ along $e$, exactly one of which admits a non-trivial action of $\mathcal{T}$, namely,

$$
\begin{aligned}
& u_{1}=\left[\begin{array}{l}
\curlywedge \\
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1} \\
& \mathbf{1} \\
& \mathbf{1}
\end{array}\right]\left[\begin{array}{lll}
\curlyvee & \curlyvee & \mathbf{1} \\
\mathbf{1} & \mathbf{1} & \curlyvee
\end{array}\right]\left[\begin{array}{lll}
\curlyvee & \curlyvee & \curlyvee
\end{array}\right] \\
& u_{1} \xrightarrow{\mathcal{T}_{\sigma_{1}}=\mathcal{T}_{11}^{2}} \quad z_{1}=\left[\begin{array}{l}
\curlywedge \\
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlyvee & \mathbf{1} \\
\mathbf{1} & \curlyvee
\end{array}\right]\left[\begin{array}{ll}

\end{array}\right]\left[\begin{array}{lll}
\curlyvee & \curlyvee & \curlyvee
\end{array}\right] \\
& \mathcal{T}_{\sigma_{2}} \searrow \quad \downarrow \mathcal{T}_{11}^{3} \\
& z_{2}=\left[\begin{array}{l}
\curlywedge \\
\curlywedge \\
\curlywedge
\end{array}\right]\left[\begin{array}{ll}
\curlyvee & \mathbf{1} \\
\mathbf{1} & \curlyvee
\end{array}\right]\left[\begin{array}{r} 
\\
\curlyvee
\end{array}\right]\left[\begin{array}{ll}
\curlywedge & \mathbf{1}
\end{array}\right] .
\end{aligned}
$$

To physically position $z_{1}$ and $z_{2}$, first note that $\mathcal{T}_{\sigma_{1}}\left(\mathcal{V}_{e}\right)=\left\{\mathcal{T}_{\sigma_{1}}\left(v_{1}\right)=1|3| 2 \mid 4\right.$, $\left.\mathcal{T}_{\sigma_{1}}\left(v_{2}\right)=1|4| 2 \mid 3\right\} \quad$ and $\quad \mathcal{T}_{\sigma_{2}}\left(\mathcal{V}_{e}\right)=\left\{\mathcal{T}_{\sigma_{2}}\left(v_{1}\right)=1|3| 4\left|2, \mathcal{T}_{\sigma_{2}}\left(v_{2}\right)=1\right| 4|3| 2\right\}$. Now $e=A_{1}\left|A_{2}\right| B_{1}=1|2| 34$ and $\sigma_{1}(e)=1324$; thus $\sigma_{1}\left(B_{1}\right)$ is not contiguous in $\sigma_{1}(e)$ and $\sigma_{1}\left(A_{2}\right)$ breaks the contiguity of $B_{1}$ in $\sigma_{1}(e)$. Thus $D_{1}=\sigma_{1}\left(A_{1}\right)$ and $\mathcal{T}\left(\sigma_{1}, e\right)=1 \mid 234$. On the other hand, $\sigma_{2}(e)=1342$; in this case $\mathcal{T}\left(\sigma_{2}, e\right)=1|34| 2$ since $\sigma_{2}$ acts on the blocks of $e$ as a (2,1)-shuffle. Consequently, we represent the vertices $z_{1}$ and $z_{2}$ as interior points of the faces $1 \mid 234$ and $1|34| 2$, respectively. To complete the subdivision of $1 \mid 234$, use the poset structure to construct new edges from $u_{1}$ to $z_{1}$ and from $z_{1}$ to $z_{2}$, and apply Proposition 9.6 to the subdivision cell $a=\left(v_{1}, u_{1}\right) \subset e$ to construct the edge $\left|\mathcal{T}_{\sigma_{1}}\left(\mathcal{V}_{a}\right)\right|$ from $1|3| 2 \mid 4$ to $z_{1}$. Then $1 \mid 234=d_{1} \cup d_{2} \cup d_{3}$ in which $\mathcal{V}_{d_{1}}=\left\{u_{1}, u_{2}, v_{2}, \mathcal{T}_{\sigma_{1}}\left(v_{2}\right), \mathcal{T}_{\sigma_{2}}\left(v_{2}\right), z_{2}, z_{1}\right\}, \mathcal{V}_{d_{2}}=\left\{u_{1}, v_{1}, \mathcal{T}_{\sigma_{1}}\left(v_{1}\right), z_{1}\right\}$, and $\mathcal{V}_{d_{3}}=$ $\left\{\mathcal{T}_{\sigma_{1}}\left(v_{1}\right), \mathcal{T}_{\sigma_{2}}\left(v_{1}\right), z_{2}, z_{1}\right\}$ (see Figure 16 and Example 9.8). An algebraic interpretation of these cells appears in the discussion of $K K_{3,3}$ following Theorem 1.

Figure 16: The subdivision of $1 \mid 234$ in $P P_{3,3}$.

## 9.4. $P P$-factorization of proper cells

Recall that an element of $\mathcal{P} \mathcal{P}_{n, m}$ is assigned to a unique directed piece-wise linear path from $(m+1,1)$ to $(1, n+1)$ in $\mathbb{N}^{2}$ with $m+n$ components of unit length (see Figure 13). Let $\Pi_{n, m}$ denote the set of all such paths and consider the map $\pi: \mathcal{P} \mathcal{P}_{n, m} \rightarrow \Pi_{n, m}$. If $u \in \operatorname{con}\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right)$, i.e., $u$ is a vertex of $\underline{m} \mid(\underline{n}+m)$, then $\pi$ restricts to a bijection $\left\{\mathcal{T}_{\sigma}(u) \mid(m, n)\right.$-shuffles $\left.\sigma\right\} \leftrightarrow \Pi_{n, m}$, and in view of Proposition $9.1, \pi$ assigns each vertex of $P_{m+n}$ to a path in $\Pi_{n, m}$ albeit non-injectively.

Now consider a proper cell $c=C_{1}|\cdots| C_{s} \subset\left|\operatorname{con} \mathcal{P} \mathcal{P}_{n, m}\right| \leftrightarrow P_{m+n}$. Each factor $C_{t}$ is a permutahedron $P_{m_{t}+n_{t}}$ whose vertices are assigned to connected subpaths of paths in $\Pi_{n, m}$. Assign $c$ to a directed piece-wise linear path $\varepsilon_{c}=\cup \varepsilon_{t}$ in the following way: Write $c=E_{1}|\cdots| E_{f} *_{(\mathbf{i} ; \mathbf{j})} F_{1}|\cdots| F_{g}$ and obtain sequences

$$
\begin{equation*}
\gamma=\left\{m+1=\gamma_{0}>\cdots>\gamma_{f}=1\right\} \quad \text { and } \quad \delta=\left\{1=\delta_{0}<\cdots<\delta_{g}=n+1\right\} \tag{20}
\end{equation*}
$$

where $\gamma_{i+1}=\gamma_{i}-\# E_{f-i}$ and $\delta_{j+1}=\delta_{j}+\# F_{g-j}$, and assign $C_{t}=E_{t}^{\prime} \cup\left(F_{t}^{\prime}+m\right)$ to the path

1. $\varepsilon_{t}:\left(\gamma_{t^{\prime}-1}, n+1-j\right) \rightarrow\left(\gamma_{t^{\prime}}, n+1-j\right)$, if $C_{t}=E_{\gamma_{t^{\prime}}}$ for some $t^{\prime}$ and maximal $j$ such that $F_{s_{1}}^{\prime}, \ldots, F_{s_{j}}^{\prime} \neq \varnothing$ and $s_{1}<\cdots<s_{j}<t$;
2. $\varepsilon_{t}:\left(i, \delta_{t^{\prime}}\right) \rightarrow\left(i, \delta_{t^{\prime}+1}\right)$, if $C_{t}=F_{\delta_{t^{\prime}}}+m$ for some $t^{\prime}$ and maximal $i$ such that $E_{s_{1}}^{\prime}, \ldots, E_{s_{i}}^{\prime} \neq \varnothing$ and $s_{1}<\cdots<s_{i}<t ;$
3. $\varepsilon_{t}:\left(\gamma_{i}, \delta_{j}\right) \rightarrow\left(\gamma_{i+1}, \delta_{j+1}\right)$, if $C_{t}=E_{\gamma_{i}} \cup\left(F_{\delta_{j}}+m\right)$ with $E_{\gamma_{i}}, F_{\delta_{j}} \neq \varnothing$ for some $i, j$.
In particular, a cell $a=A_{1} \cdots A_{k} B_{l} \cdots B_{1} \subset\left|\operatorname{con}\left(X_{m}^{n+1} \times Y_{n}^{m+1}\right)\right| \leftrightarrow \underline{m} \mid(\underline{n}+m)$ is
assigned to the path

$$
\varepsilon_{a}:\left(m+1, \beta_{0}\right) \xrightarrow{B_{1}} \cdots \xrightarrow{B_{b}}\left(m+1, \beta_{l}\right) \xrightarrow{A_{k}}\left(\alpha_{1}, n+1\right) \xrightarrow{A_{k-1}} \cdots \xrightarrow{A_{1}}\left(\alpha_{k}, n+1\right),
$$

where $\alpha=\left\{m+1=\alpha_{0}>\cdots>\alpha_{k}=1\right\}$ and $\beta=\left\{1=\beta_{0}<\cdots<\beta_{l}=n+1\right\}$ (case (3) does not occur). Thus if $c=\mathcal{T}(\sigma, a)$, the observation in (19) implies that $\gamma \subseteq \alpha$ and $\delta \subseteq \beta$.

Given a subdivision cell $d \subseteq \mathcal{T}(\sigma, a)$, there is a subdivision subcomplex $u \subset a$ such that $d=\left|\mathcal{T}_{\sigma}\left(\mathcal{V}_{u}\right)\right|$. Representing $a$ as a partition $U_{1}|\cdots| U_{s}$ of $\underline{m} \mid(\underline{n}+m)$, there is a Cartesian product decomposition $d=D_{1} \times \cdots \times D_{s}$ in which $D_{t}$ is a subdivision cell of $\mathcal{T}\left(\sigma, U_{t}\right)$. The representation $U_{1}|\cdots| U_{s}=E *_{(\mathbf{i} \mathbf{j})} F$ relates the paths associated with the vertices of $\mathcal{T}\left(\sigma, U_{t}\right)$ to the vertices of $D_{t}$, and in view of case (3) above, the vertices of $D_{t}$ are assigned to paths related to those $z \in \mathcal{T}_{\sigma}\left(\mathcal{V}_{u}\right)$ given by the action of $\mathcal{T}_{\sigma}$ on the matrix sequences $x_{\gamma_{i+1}} \cdots x_{\gamma_{i}-1} y_{\delta_{j+1}-1} \cdots y_{\delta_{j}}$ associated with the vertices of $u$ as a $\left(\gamma_{i}-\gamma_{i+1}, \delta_{j+1}-\delta_{j}\right)$-shuffle. But in every case, there is the Cartesian product decomposition

$$
D_{t}=\left(e_{y_{1}^{t}, x_{1}^{t}} \times \cdots \times e_{y_{1}^{t}, x_{p_{t}}^{t}}\right) \times \cdots \times\left(e_{y_{q_{t}}^{t}, x_{1}^{t}} \times \cdots \times e_{y_{q_{t}}^{t}, x_{p_{t}}^{t}}\right),
$$

where $e_{y_{j}^{t}, x_{i}^{t}}$ is some cell of $P P_{y_{j}^{t}, x_{i}^{t}}$ and $\left(p_{t}, q_{t}\right) \in\left\{\left(\gamma_{t^{\prime}}, n+1-j\right),\left(i, \delta_{t^{\prime}}\right),\left(\gamma_{i+1}, \delta_{j}\right)\right\}$, $p_{1}+\cdots+p_{t} \in\left\{\gamma_{t^{\prime}-1}, i, \gamma_{i}\right\}$, and $q_{1}+\cdots+q_{t} \in\left\{n+1-j, \delta_{t^{\prime}+1}, \delta_{j+1}\right\}$ (the Cartesian product decomposition of $D_{t}$ is trivial whenever $m=1$ or $n=1$ ). Therefore every proper cell $e_{n, m} \subset P P_{n, m}$ has a Cartesian matrix factorization

$$
\begin{align*}
e_{n, m}=\left[\left(e_{y_{1}^{1}, x_{1}^{1}} \times\right.\right. & \left.\left.\cdots \times e_{y_{1}^{1}, x_{p_{k}}^{1}}\right) \times \cdots \times\left(e_{y_{q_{k}}, x_{1}^{1}} \times \cdots \times e_{y_{q_{k}}^{1}, x_{p_{k}}^{1}}\right)\right] \times \cdots \\
& \times\left[\left(e_{y_{1}^{s}, x_{1}^{s}} \times \cdots \times e_{y_{1}^{s}, x_{p_{k}}^{s}}\right) \times \cdots \times\left(e_{y_{q_{k}}^{s}, x_{1}^{s}} \times \cdots \times e_{y_{q_{k}}^{s}, x_{p_{k}}^{s}} \times\right],\right. \tag{21}
\end{align*}
$$

where $p_{1}=q_{s}=1$ and $s \geqslant 2$. The decomposition in (21) is a $P P$-factorization if each factor $e_{y_{j}^{k}, x_{i}^{k}}$ lies in the family $P P$.

Indeed, each factor $e_{y_{j}^{k}, x_{i}^{k}}$ of $e_{n, m}$ has a Cartesian matrix factorization with $x_{i}^{k}+y_{j}^{k}<m+n$, and we may inductively apply the decomposition in (21) to obtain a decomposition of $e_{n, m}$ as a Cartesian product of polytopes in the family PP. This decomposition involves Cartesian products in two settings: Those within bracketed quantities correspond to tensor products of entries in a bisequence monomial (controlled by $\Delta_{P}^{(k)}$ ) and those between bracketed quantities correspond to $\Upsilon$-products of bisequence monomials. And indeed, this decomposition is encoded by a leveled tree $\Psi\left(e_{n, m}\right)$ constructed in the same way we constructed $\Psi(\phi(\xi))$ for $\xi \in \mathfrak{G}$. Whereas the levels and the leaves of $\Psi(\phi(\xi))$ are bisequence and $\Theta$-factorizations, the levels and leaves of $\Psi\left(e_{n, m}\right)$ are Cartesian matrix and $P P$-factorizations.

Example 9.8. Refer to Example 9.7 and consider the codimension 1 cell $c=C_{1} \mid C_{2}=$ $1 \mid 234 \subset P_{2+2}$. Write $c=E_{1}\left|E_{2} * F_{1}=1\right| 2 * 12$ and obtain $\gamma_{0}=3, \gamma_{1}=2, \gamma_{2}=1$; and $\quad \delta_{0}=1, \quad \delta_{1}=3$. Then $C_{1}=E_{1}^{\prime} \cup F_{1}^{\prime}=E_{1} \cup \varnothing \quad$ and $\quad C_{2}=E_{2}^{\prime} \cup\left(F_{2}^{\prime}+2\right)=$ $E_{2} \cup\left(F_{1}+2\right)$. The path $C_{1}$ is assigned to the path component $\varepsilon_{1}:(2,3) \rightarrow(1,3)$ and $C_{2}$ is assigned to $\varepsilon_{2}:(3,1) \rightarrow(2,3)$; in this case there is the action of a $\left(\gamma_{0}-\gamma_{1}\right.$, $\left.\delta_{1}-\delta_{0}\right)=(1,2)$-shuffle on $x_{\gamma_{0}-1} y_{\delta_{1}-1} y_{\delta_{0}}=x_{2} y_{2} y_{1}$, which generates (classes of ) vertices of $C_{2}$. Let $u$ be the subdivision subcomplex of $1|2| 34$ consisting of the two edges $\left(u_{1}, u_{2}\right)$ and $\left(u_{2}, v_{2}\right)$ (see Figure 16). Then for $i=1,2,3$, the subdivision cell
$d_{i}=D_{1}^{i} \times D_{2}^{i}$, where $D_{1}^{i}=C_{1}=P_{1}$ is a vertex and $D_{2}^{i} \subset C_{2}$ has the form $D_{2}^{i}=$ $e_{3,2}^{i} \times e_{3,1}^{i}$, where $\left(\operatorname{dim} e_{3,2}^{1}, \operatorname{dim} e_{3,1}^{1}\right)=(2,0)$ and $\left(\operatorname{dim} e_{3,2}^{i}, \operatorname{dim} e_{3,1}^{i}\right)=(1,1)\left(e_{3,2}^{1}=\right.$ $P P_{2,1}$ is a heptagon and $e_{3,1}^{1}$ is a vertex of $P P_{2,0} ; e_{3,2}^{i}$ is an edge of $P P_{2,1}$ and $e_{3,1}^{i}=P P_{2,0}$ for $i=2,3$ ). Thus up to homeomorphism we have

$$
\begin{aligned}
d_{1} & =\left[P P_{0,1} \times P P_{0,1} \times P P_{0,1}\right] \times\left[P P_{2,1} \times\left(P P_{1,0} \times P P_{1,0}\right)\right] \\
d_{2} & =\left[P P_{0,1} \times P P_{0,1} \times P P_{0,1}\right] \times\left[\left(P P_{1,1} \times P P_{1,0}\right) \times P P_{2,0}\right] \\
d_{3} & =\left[P P_{0,1} \times P P_{0,1} \times P P_{0,1}\right] \times\left[\left(P P_{1,0} \times P P_{1,1}\right) \times P P_{2,0}\right] .
\end{aligned}
$$

9.5. The projection $\vartheta \vartheta: P P \rightarrow K K$

The final piece of our construction establishes a geometric interpretation of the projection $\vartheta \vartheta: P P_{m, n} \rightarrow K K_{n+1, m+1}$ induced by the quotient map $\mathcal{P} \mathcal{P}_{n, m} \rightarrow$ $\mathcal{K} \mathcal{K}_{n+1, m+1}$. Let $\mathcal{P}_{n, m}=\operatorname{con\mathcal {P}} \mathcal{P}_{n, m}, P_{n, m}=\left|\mathcal{P}_{n, m}\right|$, and $K_{n+1, m+1}=\left|\mathcal{P}_{n, m} / \sim\right|$; we obtain $K K_{n+1, m+1}$ as the subdivision of $K_{n+1, m+1}$ that commutes the following diagram:

(the horizontal maps are non-cellular homeomorphisms induced by the subdivision process). We identify the cellular chains $C_{*}(K K)$ with the free matrad $\mathcal{H}_{\infty}$ and prove that the restriction of the free resolution of prematrads $\rho^{\text {pre }}: F^{\text {pre }}(\Theta) \rightarrow \mathcal{H}$ to $\mathcal{H}_{\infty}$ is a free resolution in the category of matrads.

To simplify notation, we suppress the subscripts of $\vartheta_{n, m}: P_{n, m} \rightarrow K_{n+1, m+1}$ when $m$ and $n$ are clear from context. Since $\left|\mathcal{P}_{n, m}\right|=P_{n, m}=P_{m+n}$, a proper face $e \subset P_{n, m}$ is a product of permutahedra

$$
e=P_{n_{1}, m_{1}} \times \cdots \times P_{n_{s}, m_{s}}
$$

and projects to a product

$$
\tilde{e}=\vartheta(e)=\vartheta\left(P_{n_{1}, m_{1}}\right) \times \cdots \times \vartheta\left(P_{n_{s}, m_{s}}\right)=K_{n_{1}+1, m_{1}+1} \times \cdots \times K_{n_{s}+1, m_{s}+1} .
$$

The fact that $\vartheta_{n, m}=I d$ when $1 \leqslant m, n \leqslant 2$ implies $K_{n+1, m+1}=P_{m+n}$; also, $K_{n, 2} \cong$ $K_{2, n}$ is the multiplihedron $J_{n}$ for all $n$ (see [14], [3], [10], [9]). The faces $24 \mid 13$ and $1|24| 3$ of $P_{3,1}$ are degenerate in $K_{4,2}$ since $\vartheta_{3,1}(24 \mid 13)=24|1| 3$ and $\vartheta_{3,1}(1|24| 3)=$ $1|2| 4 \mid 3$; and dually, the faces $24 \mid 13$ and $2|13| 4$ of $P_{1,3}$ are degenerate in $K K_{2,4}$ since $\vartheta_{1,3}(24 \mid 13)=2|4| 13$ and $\vartheta_{1,3}(2|13| 4)=2|1| 3 \mid 4$. Observe that the product cell

$$
K_{m+1} \times K_{n+1}=\vartheta\left(P_{m} \times P_{n}\right) \subset \vartheta\left(P_{m+n}\right)=\vartheta\left(P_{n, m}\right)=K_{n+1, m+1}
$$

admits the ( $m, n$ )-subdivision

$$
K_{m+1}^{(n)} \times K_{n+1}^{(m)}=\vartheta \vartheta\left(P_{m}^{(n)} \times P_{n}^{(m)}\right) \subset \vartheta \vartheta\left(P P_{n, m}\right)=K K_{n+1, m+1} .
$$

Example 9.9. The (2,2)-subdivision $K_{3}^{(2)} \times K_{3}^{(2)}$ of the face $\vartheta_{2,2}(12 \mid 34)=K_{3} \times K_{3} \subset$ $K_{3,3}$ produces 9 cells of $K K_{3,3}$ (see Figures 14 and 20); the (3,1)-subdivision $K_{2}^{(3)} \times K_{4}^{(1)}$ of the face $\vartheta_{1,3}(1 \mid 234)=K_{2} \times K_{4} \subset K_{4,2}$ produces 6 cells of $K K_{4,2}$ (see Figures 3 and 21).

Define

$$
\widetilde{\mathcal{B S}}_{n+1, m+1}=\left(\vartheta_{*} \times \vartheta_{*}\right)\left(\mathcal{B S _ { n , m }}\right) .
$$

Example 9.10. The biassociahedron $K K_{3,3}=P P_{2,2}$ and has 44 vertices, 16 of which lie in $12 \mid 34$. Of these 16 vertices, 4 lie in $\mathcal{P}_{2,2}$ and generate the other 19 vertices of $K_{3,3}=P_{4}$; another 4 lie $\widetilde{\mathcal{B S}}_{3,3}$ and generate the 8 remaining vertices of $K K_{3,3}$ (see Figure 20). By contrast, $K K_{4,2}$ is a non-trivial quotient of $P P_{3,1}$. As in Tonks' projection $\vartheta_{0}: P_{n} \rightarrow K_{n+1}$, we identify faces of $P P_{3,1}$ indexed by isomorphic graphs (forgetting levels) as pictured in Figure 17. Here an equivalence class of graphs, which labels a face of the target interval, contains the three graphs horizontally to its left.

Figure 17: Projection of a degenerate square in $P P_{3,1}$ to $K K_{4,2}$.

The biassociahedra $K K_{1,1}, K K_{2,1}$ and $K K_{1,2}$ are isolated vertices and correspond to the free matrad generators 1, $\theta_{1}^{2}$ and $\theta_{2}^{1}$, respectively. The biassociahedra $K K_{n, m}$ with $4 \leqslant m+n \leqslant 6$ are pictured in Figures 18 through 22 below and labelled by partitions and (co)derivation leaf sequences. Note that $K K_{n, m} \cong K K_{m, n}$ for all $m, n \geqslant 1$ and $K K_{2, m}$ is a subdivision of $J_{m}$ when $m \geqslant 3$.

If $\tilde{e}_{n, m}$ is a proper face of $K K_{n, m}$, the decomposition in (21) induces a product decomposition of the form

$$
\begin{align*}
& \tilde{e}_{n, m}=\left[\left(\tilde{e}_{y_{1}^{1}, x_{1}^{1}} \times \cdots \times \tilde{e}_{y_{1}^{1}, x_{p_{k}}^{1}}\right) \times \cdots \times\left(\tilde{e}_{y_{q_{k}}^{1}, x_{1}^{1}} \times \cdots \times \tilde{e}_{y_{q_{k}}^{1}, x_{p_{k}^{1}}^{1}}\right)\right] \\
& \times \cdots \times\left[\left(\tilde{e}_{y_{1}^{s}, x_{1}^{s}} \times \cdots \times \tilde{e}_{y_{1}^{s}, x_{p_{k}}^{s}}\right) \times \cdots \times\left(\tilde{e}_{y_{q_{k}}^{s}, x_{1}^{s}} \times \cdots \times \tilde{e}_{y_{q_{k}}^{s}, x_{p_{k}}^{s}} \times,\right.\right. \tag{22}
\end{align*}
$$

where $p_{1}=q_{s}=1$ and $s \geqslant 2$. Here " $\times$ " within a bracketed quantity corresponds to the tensor product in a bisequence monomial (controlled by certain iterations of $\Delta_{P}$ and the product cell within $k^{t h}$ bracket is thought of as a subdivision cell of $K_{n_{k}+1, m_{k}+1}$ in the decomposition of $e_{n, m}$ in (21)) and " $\times$ " between bracketed quantities corresponds to an $\Upsilon$-product, and each $\tilde{e}_{y_{j}^{k}, x_{i}^{k}}$ has the form given by (22) with $x_{i}^{k}+y_{j}^{k}<m+n$.

We distinguish between two kinds of faces in (22). A Type I face is detected by the diagonal $\Delta_{P}$ and its representation in (22) has $\left(p_{k}, q_{k}\right)>(1,1)$ for all $k$; thus $\Delta_{P}$ is only involved in forming the Cartesian products in parentheses. A Type II face $\tilde{e}_{n, m}$
is independent of $\Delta_{P}$ and its representation in (22) satisfies $\left(p_{k}, q_{k}\right)=(1,1)$ for all $k$; thus $\tilde{e}_{n, m}$ has the form $K K_{n, i_{2}} \times K_{i_{2}-i_{1}+1} \times \cdots \times K_{i_{s}-i_{s-1}+1}, 1 \leqslant i_{2}<\cdots<i_{s}=m$, or $K_{j_{0}-j_{1}+1} \times \cdots \times K_{j_{s-2}-s-1+1} \times K K_{j_{s-1}, m}, 1 \leqslant j_{s-1}<\cdots<j_{0}=n$. In particular, a codimension 1 face (when $s=2$ ) has the form $K K_{n, i} \times K_{m+1-i}$ or $K_{n+1-j} \times K K_{j, m}$. Consequently, each cell $\tilde{e}_{n, m} \subset K K_{n, m}$ is associated with a levelled tree $\Psi\left(\tilde{e}_{n, m}\right)$, whose levels are representations given by (22) and whose leaves are $K K$-factorizations.

The assignment $\iota: \theta_{p}^{q} \mapsto K K_{q, p}$, which preserves levels, induces a set map

$$
\begin{equation*}
\iota: \mathfrak{G}_{n, m} \rightarrow\left\{\text { faces of } K K_{n, m}\right\} \tag{23}
\end{equation*}
$$

that sends balanced factorizations to Cartesian matrix factorizations and has the following properties:
(i) The restriction of $\iota$ to 0 -dimensional module generators of $F_{n, m}(\Theta)$ establishes a bijection with vertices of $K K_{n, m}$ by replacing $\theta_{2}^{1}$ with $\curlywedge$ and $\theta_{1}^{2}$ with $\curlyvee$ in each entry of $\Psi(\beta)$.
(ii) There is a location map

$$
\begin{equation*}
\tilde{\iota}: \mathfrak{G}_{q+1, p+1} \rightarrow\left\{\text { faces of } P_{p+q}\right\} \tag{24}
\end{equation*}
$$

that commutes the following diagram of set maps

$$
\begin{array}{ccc}
\left.\begin{array}{c}
\mathfrak{G}_{q+1, p+1} \\
\iota \downarrow \\
\text { es of } K K_{q+1, p+1}
\end{array}\right\} & \xrightarrow{\tilde{\iota}} & \begin{array}{c}
\left\{\text { faces of } P_{p+q}\right\} \\
\downarrow \vartheta_{q, p}
\end{array} \\
& \xrightarrow{\nu} & \left\{\text { faces of } K_{q+1, p+1}\right\}
\end{array}
$$

where $\nu$ sends a cell of $K K$ to the cell of $K$ of minimal dimension containing it. Indeed, if $\beta=C_{s} \cdots C_{1} \in \mathcal{B}$ is the balanced representative of $\theta$ with $C_{k} \in \mathbf{G}_{\mathbf{x}^{k}}^{\mathbf{y}^{k}}$, consider the (co)derivation leaf sequences $\left(\left(\mathbf{x}^{1}, \mathbf{y}^{1}\right), \ldots,\left(\mathbf{x}^{s}, \mathbf{y}^{s}\right)\right)$, and let $\mathbf{x}^{i_{1}}, \ldots, \mathbf{x}^{i_{k}}$ and $\mathbf{y}^{j_{1}}, \ldots, \mathbf{y}^{j_{l}}$ be the subsequences obtained by removing all $\mathbf{x}^{i}, \mathbf{y}^{j}=\mathbf{1}$. Thinking of these subsequences as row and column descent sequences, consider the corresponding faces $A=A_{1}|\cdots| A_{k} \subset P_{m-1}$ and $B=$ $B_{1}|\cdots| B_{l} \subset P_{n-1}$ and set

$$
e_{\theta}=\chi(A) *_{(\mathbf{i}, \mathbf{j})} B \subset P_{m+n-2}
$$

where $\chi: P_{m-1} \rightarrow P_{m-1}$ is the cellular involution defined by $\chi\left(A_{1}|\cdots| A_{k}\right)=$ $\left(m-A_{k}\right)|\cdots|\left(m-A_{1}\right)$ and $(\mathbf{i} ; \mathbf{j})=\left(i_{1}<\cdots<i_{k} ; j_{1}<\cdots<j_{l}\right)$. Then $e_{\theta}$ is the unique cell of minimal dimension $\geqslant k$ such that $\iota(\theta) \subset \vartheta_{n-1, m-1}\left(e_{\theta}\right)$; in particular, when $s=2, \mathbf{x}^{1}=\mathbf{x}$ and $\mathbf{y}^{2}=\mathbf{y}$, and we recover the special cell $e_{\theta}=e_{(\mathbf{y}, \mathbf{x})}$ defined in (13). Thus, the term "location map" suggests the fact that $\tilde{\iota}$ points out the position of the image cells $\iota(\theta)$ with respect to cells of the permutahedron $P_{m+n}$. Under $\tilde{\iota}$, the associativity of the $\Upsilon$-product on $\mathfrak{G}$ is compatible with the associativity of the partitioning procedure in $p+q$ by which $a_{1}|\cdots| a_{k}$ is obtained from the (ordered) set $a_{1} \cdots a_{k}$ by inserting bars: Given $\theta, \zeta \in \mathfrak{G}$, let $\xi \in \mathfrak{G}$ be the component shared by $\partial(\theta)$ and $\partial(\zeta)$ in $\mathcal{H}_{\infty}$. Then $\vartheta(\tilde{\iota}(\xi)) \subset \vartheta(\tilde{\iota}(\theta)) \cap \vartheta(\tilde{\iota}(\zeta))$ in $K_{q+1, p+1}=\vartheta\left(P_{p+q}\right)$ (see Example 9.12).
(iii) Let $\operatorname{dim} \theta=k$ and let $\sigma_{\theta}$ be the set of all 0 -dimensional elements of $\mathcal{H}_{\infty}$ obtained by all possible compositions $\partial_{i_{k}} \cdots \partial_{i_{1}}(\theta)$ where $\partial_{i}$ is a component of $\partial=\sum_{i} \partial_{i}$. Then $\iota(\theta)$ is the $k$-face of $K K_{n, m}$ spanned on the set $\iota\left(\sigma_{\theta}\right)$.
(iv) If $(m, n) \in\{(2,0),(1,1),(0,2)\}$ in item (ii) and $k=1$ in item (iii), then $K K_{n+1, m+1}=K_{n+1, m+1}=P_{m+n}$ is an interval and (ii) agrees with (iii) under the equality $\iota=\left.\tilde{\iota}\right|_{\mathfrak{G}_{n+1, m+1}}$ for $m+n \leqslant 2$.
Remark 9.11. Since $\tilde{\iota}$ is not surjective, the action of the (pre)matrad axioms on Type II generators forces us to obtain $K K_{n+1, m+1}$ as a quotient of $P P_{n, m}$ modulo combinatorial relations in $P P_{n, m}$ as indicated in Figure 16 above, and thereby extend the equality $K_{n+1}=P_{n} / \sim$ induced by Tonks' projection (see Theorem 9.13 below).

Example 9.12. The action of the map $\theta \rightarrow \tilde{\iota}(\theta)$ involving associativity is illustrated by the example in (10):

$$
((221),(31)) \rightarrow 146 \mid 2357 \text { and }((41),(211)) \rightarrow 12456 \mid 37
$$

while

$$
(((221),(2)),((21),(21)),((2),(211))) \rightarrow 146|25| 37
$$

(on left-hand sides only (co)derivation leaf sequences of underlying matrad module generator are shown). Also, from Example 6.2 we have

$$
C_{3} C_{2} C_{1} \xrightarrow{\tilde{\iota}} 357|14| 26 .
$$

The properties above imply that $\iota$ is a bijection so that $\mathcal{C}_{n, m}$ indexes the faces of $K K_{n, m}$. Define the boundary map in the cellular chain complex $C_{*}\left(K K_{n, m}\right)$ by

$$
\begin{equation*}
\partial\left(X_{m}^{n}\right)=\sum_{(\alpha, \beta) \in \mathcal{A} \mathcal{B}_{m, n}}(-1)^{\epsilon+\epsilon_{\alpha}+\epsilon_{\beta}} e_{\alpha, \beta} \tag{25}
\end{equation*}
$$

where $\epsilon$ is the sign of the cell $e_{(\mathbf{y}, \mathbf{x})} \subset P_{n-1, m-1}$ defined by (13). This sign reflects the fact that the sign of a subdivision cell in the boundary inherits (as a component) the sign of the boundary. Therefore, we immediately obtain:

Theorem 9.13. For each $m, n \geqslant 1$, there is a canonical isomorphism of chain complexes

$$
\begin{equation*}
\iota_{*}:\left(\mathcal{H}_{\infty}\right)_{n, m} \xrightarrow{\approx} C_{*}\left(K K_{n, m}\right) \tag{26}
\end{equation*}
$$

extending the standard isomorphisms

$$
\mathcal{A}_{\infty}(n)=\left(\mathcal{H}_{\infty}\right)_{n, 1} \stackrel{\approx}{\approx} C_{*}\left(K K_{n, 1}\right)=C_{*}\left(K_{n}\right)
$$

and

$$
\mathcal{A}_{\infty}(m)=\left(\mathcal{H}_{\infty}\right)_{1, m} \xrightarrow{\approx} C_{*}\left(K K_{1, m}\right)=C_{*}\left(K_{m}\right) .
$$

In other words, the cellular chains of the biassociahedra $K K$ realize the free matrad resolution $\mathcal{H}_{\infty}$ of the bialgebra matrad $\mathcal{H}$. In particular, consider the submodule $\tilde{\mathcal{H}}_{\infty} \subset \mathcal{H}_{\infty}$ spanned on the generating set $\tilde{\Theta}$ fixed by summing of all (distinct) elements of $\mathfrak{G}$ in $\mathcal{H}_{\infty}$ that have the same leaf sequence form. Then (24) induces an isomorphism

$$
\begin{equation*}
(\vartheta \circ \tilde{\iota})_{*}:\left(\tilde{\mathcal{H}}_{\infty}\right)_{n, m} \stackrel{\approx}{\approx} C_{*}\left(K_{n, m}\right) \tag{27}
\end{equation*}
$$

by $(\vartheta \circ \tilde{\iota})_{*}(\tilde{\theta})=\vartheta\left(\tilde{\iota}\left(\theta_{s}\right)\right)$, where $\theta_{s} \in \mathfrak{G}_{n, m}$ is any summand component of $\tilde{\theta} \in \tilde{\Theta}$, and
the following diagram commutes:

$$
\begin{array}{clcc}
\left(\tilde{\mathcal{H}}_{\infty}\right)_{n, m} & \longrightarrow & \left(\mathcal{H}_{\infty}\right)_{n, m} \\
(\vartheta \circ \tilde{\iota})_{*} \downarrow \approx & & \approx \downarrow \iota_{*} \\
C_{*}\left(K_{n, m}\right) & \underset{\nu \#}{ } & C_{*}\left(K K_{n, m}\right) .
\end{array}
$$

Example 9.14. We have $\tilde{\iota}((111),(21))=1 \mid 234 \subset P_{4}$, and apply Example 9.8 for which bijection (26) implies

$$
\begin{aligned}
& {\left[\begin{array}{c}
\theta_{2}^{1} \\
\theta_{2}^{1} \\
\theta_{2}^{1}
\end{array}\right]\left[\begin{array}{ll}
\theta_{2}^{3} & {\left[\begin{array}{c}
\mathbf{1} \\
\theta_{1}^{2}
\end{array}\right] \theta_{1}^{2}}
\end{array}\right] \quad \leftrightarrow \quad d_{1}} \\
& {\left[\begin{array}{c}
\theta_{2}^{1} \\
\theta_{2}^{1} \\
\theta_{2}^{1}
\end{array}\right]\left[\left[\begin{array}{c}
\theta_{2}^{2} \\
\theta_{2}^{1}
\end{array}\right]\left[\begin{array}{lll}
\theta_{1}^{2} & \theta_{1}^{2}
\end{array}\right] \quad \theta_{1}^{3}\right] \leftrightarrow d_{2}} \\
& {\left[\begin{array}{c}
\theta_{2}^{1} \\
\theta_{2}^{1} \\
\theta_{2}^{1}
\end{array}\right]\left[\left[\begin{array}{c}
\theta_{1}^{2} \\
1
\end{array}\right] \theta_{2}^{2} \quad \theta_{1}^{3}\right] \quad \leftrightarrow \quad d_{3} .}
\end{aligned}
$$

The edge $\left(1|3| 2 \mid 4, z_{1}\right)$ in Figure 16 is the intersection $d_{2} \cap d_{3}$ corresponding to

$$
A_{2} A_{1}=\left[\begin{array}{c}
\theta_{2}^{1}  \tag{28}\\
\theta_{2}^{1} \\
\theta_{2}^{1}
\end{array}\right]\left[\left(\left[\begin{array}{c}
\theta_{1}^{2} \\
1
\end{array}\right]\left[\begin{array}{c}
\theta_{2}^{1} \\
\theta_{2}^{1}
\end{array}\right]\left[\theta_{1}^{2} \theta_{1}^{2}\right]\right) \theta_{1}^{3}\right] \in \mathcal{B}_{3,3}
$$

The following proposition applies Proposition 6.14 to reformulate Theorem 9.13 in terms of the ©-operation defined in (15) for $(M, \gamma)=\left(F^{\mathrm{pre}}(\Theta), \gamma\right)$.

Proposition 9.15. Let $\left(F^{\mathrm{pre}}(\Theta), \gamma\right)$ be the free prematrad and $\left(\mathcal{H}_{\infty}, \partial\right)$ be the $A_{\infty}$-matrad. If $\xi=\left[\left(\theta \backslash \theta_{m}^{n}\right) \odot\left(\theta \backslash \theta_{m}^{n}\right)\right]_{n, m}$ with $m n \geqslant 3$, the components of $\xi$ fit the boundary of $K K_{n, m}$ and $\partial(\xi)=0$.

Thus, an $A_{\infty}$-bialgebra structure on a DGM $H$ is defined by a morphism of matrads $\mathcal{H}_{\infty} \rightarrow U_{H}$ (compare [11]).

In our forthcoming paper [9], we construct the theory of relative matrads and use it to define a morphism of $A_{\infty}$-bialgebras. Using relative $A_{\infty}$-matrads, we prove that over a field, the homology of every biassociative DG bialgebra admits a canonical $A_{\infty}$-bialgebra structure.

For $K K_{2,2}$ :

$$
\begin{aligned}
& 1 \mid 2 \leftrightarrow{ }_{11}^{11}=\gamma\left(\theta_{2}^{1} \theta_{2}^{1} ; \theta_{1}^{2} \theta_{1}^{2}\right) \\
& 2 \mid 1 \leftrightarrow{ }_{2}^{2}=\gamma\left(\theta_{1}^{2} ; \theta_{2}^{1}\right)
\end{aligned}
$$

Figure 18: The biassociahedron $K K_{2,2}$ (an interval)

For $K K_{3,2}$ :

$$
\begin{aligned}
& 1 \mid 23 \leftrightarrow{ }_{11}^{111}=\gamma\left(\theta_{2}^{1} \theta_{2}^{1} \theta_{2}^{1} ; \gamma\left(\theta_{1}^{2} \theta_{1}^{1} ; \theta_{1}^{2}\right) \theta_{1}^{3}+\theta_{1}^{3} \gamma\left(\theta_{1}^{1} \theta_{1}^{2} ; \theta_{1}^{2}\right)\right) \\
& 13 \mid 2 \leftrightarrow{ }_{11}^{12}=\gamma\left(\theta_{2}^{1} \theta_{2}^{2} ; \theta_{1}^{2} \theta_{1}^{2}\right) \\
